CRITERIA FOR THE DIAGNOSIS OF CERTAIN TUBERCULODERMS

Chairman's Address

HENRY E. MICHELSON, M.D.
Minneapolis

All dermatologists are aware of the great progress that has been made in recent years in our knowledge of cutaneous tuberculosis. We have kept abreast of the advances with the knowledge of tuberculosis elsewhere and have followed the research in related fields. We have attempted to apply the new facts as each was established to what was known about cutaneous tuberculosis, but despite our considerable present knowledge, despite all the advances in the fields of allergy and immunology, we have been unable to find an explanation for the great variance in the morphologic aspects of the various tuberculoderms as we know them today.

The finding of the tubercle bacillus in lupus vulgaris lesions, both by culture and inoculation, disclosed that this cutaneous disease is in general tuberculous. This was a great advance, but it did not explain why in certain tuberculous patients there should develop such a slow, almost benign, form of cutaneous tuberculosis, even though its manifestation in the skin was a destructive and serious malady in itself. Other cutaneous diseases less destructive than lupus vulgaris had been suspected of being closely related to lupus, but proof of their tuberculous causation was slow in coming. Gradually evidence was accumulated that some of these, for example acnitis, were also caused by the tubercle bacillus, and one by one a number of diverse cutaneous conditions were proved to be of tuberculous causation or, because of certain constant observations, were strongly suspected of being tuberculous. When this relationship, real or suspected, of tuberculosis was applied to a large series of poorly described cutaneous lesions, a nosologic terminology evolved which to this day makes the subject incredibly involved and complex.

In 1896 Darier propounded his theory of the tuberculids, and a new nomenclature was evolved. Lesions which were suspected of being tuberculous, but in which the tubercle bacillus could rarely if ever be found, were called "tuberculids," and the enthusiasm of some allowed a large number of cutaneous conditions to be included in this ill defined nosologic group.

As certain cutaneous lesions which either had been proved to be tuberculous or were still strongly suspected of being so became better known and were reported with greater regularity, an effort was made to classify them. Some students of the subject decided that certain types arose from inoculation in virgin soil, and they classified these types as external cutaneous tuberculosis, while other forms developed from endogenous infections and these they called internal types. Other classifications were based on the mode of spread and on the suspected manner of sowing of the bacilli in the skin. The way the patient who harbored various tuberculous lesions reacted to tuberculin provided explanation for the pathogenesis of certain types and hence another means of classification. The course and prognosis of the disease revealed the close relationship of some of these diverse conditions.

Regardless of which classification one accepts, it must be admitted that the behavior, the morphologic and histologic aspects and the prognosis of each well established form of cutaneous tuberculosis is peculiar to that form and that we must have as thorough an understanding of each particular form as present knowledge allows. Why do these various forms exist? To account for such dissimilarities it is necessary to presuppose different types of reaction between the bacilli and the tissues and to accept as an explanation the theory that there are individual peculiarities of the tissue in different persons.

A given pathogenic organism provokes, in the main, a fairly constant reaction in the tissues, as is so well demonstrated in histologic study of the reactions provoked by the Treponema pallidum. The tubercle bacillus also brings about a tissue response which is often easily recognizable. However, histologic analysis of a tuberculoderm, taking into consideration the epidermis, connective tissue, lymph vessels, blood vessels, glands and other parts, demonstrates that there is a certain uniformity in the individual tissue alternates throughout most of these lesions and that the pathologic changes do not account for the structure to any great extent. The quantitative value of the reaction seems more important than the qualitative, so that, by and large, the histologic observations of tuberculoderms do not explain either their presence or their form. The great morphologic variation must admit different types or degrees of reaction, but minute analysis invariably reveals the stamp of tuberculosis. The differences must rest, therefore, with the peculiarities of the tissues and all of the forces of tissue resistance, organism virulence, anatomic location and, of course, many unexplained phenomena.

To be able to diagnose, understand and treat the various forms of cutaneous tuberculosis as we know them today demands exhaustive study of the known facts about each of these various forms, and even then our knowledge must be somewhat adapted to the case at hand. Isolated well established observations are valuable, even though it is difficult to understand why certain things pertain when a case is viewed as representative of a type in a classification.

Director, Division of Dermatology, University of Minnesota.

Read before the Section on Dermatology and Syphilology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

Therefore, I propose to review the established facts about a few of the tuberculoderms with the hope that we may attain a more uniform terminology and understanding when we are discussing these diseases.

LUPUS VULGARIS

Lupus vulgaris is the most important of the tuberculous conditions of the skin. Since it does not occur frequently in America, it is not so well known here as it is in Europe, where it is endemic in certain areas and is of vast social and economic importance. Lupus vulgaris is a term which is applied to a great many *variations of a basic condition*; hence a knowledge of the disease must include an understanding of its inception and an appreciation of its metamorphoses which result in such diverse morphologic forms and, unfortunately, in such an array of names. It must be constantly borne in mind that the different names do not imply a different disease, but merely varieties of one and the same process. *In fact, it would be better if all forms were called lupus vulgaris, with the type which briefly describes the chief variation following in parentheses; for example: lupus vulgaris (tumidus type).*

Lupus vulgaris always begins with the formation of a primary or elementary lesion. When the patient is first seen, the disease may be so altered that the beginning lesion cannot be found or pointed out by the patient; nevertheless there had been a primary lesion. It is called the lupus nodule, which is in reality a histologic designation; clinically it appears as a small group of lupus nodules, comprised microscopically of a primary lupus macule or papule, or even a small node. The primary lesion of lupus vulgaris must not be confused with a microscopic tubercle or with the primary lesion of tuberculosis as seen in the lung. It is merely the initial reaction to the tubercle bacillus in the skin of a person who, for various inexplicable reasons, is a fit subject for this peculiar form of cutaneous tuberculosis known as lupus vulgaris. This individual susceptibility rests on many factors about which we may speculate, but the reason that in a person infected with tubercle bacilli there develops a particular type of cutaneous tuberculosis simply is not known. The general laws that govern the reaction of the human organism to tuberculosis must pertain in cutaneous tuberculosis, but it is more difficult to apply them and to observe the various stages and changes in the integument. The state of allergy and the degree of immunity are closely related to the morphologic manifestations in cutaneous tuberculosis, but the relationship is not so well understood as it is in the lungs. The person in whom lupus vulgaris develops evidently has a high degree of allergy but low immunity and resistance. There is a *decided defense reaction against* invasion of the bacilli, but an inability to overcome the invaders or even to keep the disease from advancing. For this reason, lupus vulgaris is in most instances a chronic slowly progressive [illegible] as a small lupus nodule, growing [illegible]rming an ever enlarging plaque, the character of which changes *when the inflammation brings about noticeable alterations* in the epidermis or cutis. If the epidermis becomes hyperkeratotic, the lesion assumes a verrucous character, or if lymphatic stasis is pronounced in the corium the lesion becomes tumefied, and so on, but the basic process is the same, a tuberculous inflammation beginning and extending in the cutis and having certain characteristics which are unique for lupus vulgaris.

Lupus vulgaris is distinctly a class disease. It is rarely seen in the stratum of society which enjoys ample food, hygienic surroundings and protection from close contact with an infective source, such as neglected and undetected tuberculosis in the milieu of a person. Geographic locations and climates also play an important role. Lupus vulgaris occurs endemically in regions which have a moist cool climate with a relatively small number of hours of sunlight per year. It is an extremely rare disease in the tropics.

Lupus vulgaris frequently begins in childhood, especially in endemic areas, although this is not so often true of the sporadic cases seen in America. This predilection may be due to certain anatomic properties of the skin, mucous membranes and lymphatic apparatus of childhood, and one may readily appreciate the greater opportunity for infection of a child in a household in which there is tuberculosis.

That lupus vulgaris is due to tuberculosis seems to be well established, even though it is difficult to demonstrate the bacillus in lupous tissue. Numerous positive results of animal inoculations, the nature of the pathologic changes within the lesion, the patient's positive reactions to tuberculin and the identification of the organism by many investigators all seem to leave no doubt of the tuberculous nature of this disease.

The disease, as previously stated, begins as a small collection of miliary tuberculous nodules situated in the papillary portion of the cutis, or even deeper. They first appear as a small circumscribed flat red or brown area of infiltrate which cannot be obliterated by glass pressure (diascopy), but later appear paler and often have the apple jelly color which is so traditionally quoted as being characteristic of lupus vulgaris. The gross nodule is soft and easily permits penetration with a pointed probe. Growth is slow but steady, and the small node soon becomes a round or oval area which may be either smooth or covered with a fine scale. The plane or scaly lesion is characteristic for lupus vulgaris in childhood. As growth progresses, the lesions usually become more papular and elevated and the outline changes; in some a disk-like plaque results, and in others the peripheral growth is more rapid and, with some degree of healing in the center of the lesion, becomes annular or serpiginous. If growth is rapid and the process intense, the lesion assumes the appearance of an elevated tumor, sometimes becoming fungoid. If the process involves chiefly the papillary layer and the epidermis is affected, the lesion becomes verrucous or papillomatous, but if the patient is a candidate for severe disease, ulceration with secretion and crust formation quickly ensues. Lupus vulgaris lesions always have sharp boundaries, and the surrounding tissue may appear normal, or a few sentinel lupus nodules may stand out at the periphery in the normal tissue.

The further growth and development of an initial area of lupus vulgaris may proceed in a variety of ways. The plaque may attain a certain size and then remain stationary in size and type. If growth continues, it is very slow, and gradually scar formation takes place, beginning in the center of the plaque but almost never being complete, islands of characteristic lupus tissue being discernible in the scar. Another possibility is the appearance of new plaques in different parts of the body. But the commoner course of events is that the plaque extends in area and changes in character. Long-standing plaques either ulcerate and become crusted or become covered with a thick dry scale. Face lesions are prone to become tumidified because of stasis, while plaques on the body become verrucous. As in every tuberculous process, so also does lupus have the tendency to form fibrous scar. The scar of a plane plaque is often soft and smooth, but the scarring which follows ulcerating and destructive lupus vulgaris lesions may lead to unsightly and handicapping deformity. About the nose, mouth and eyes, and also in the hands, the scars may cause actual loss of function and great disability.

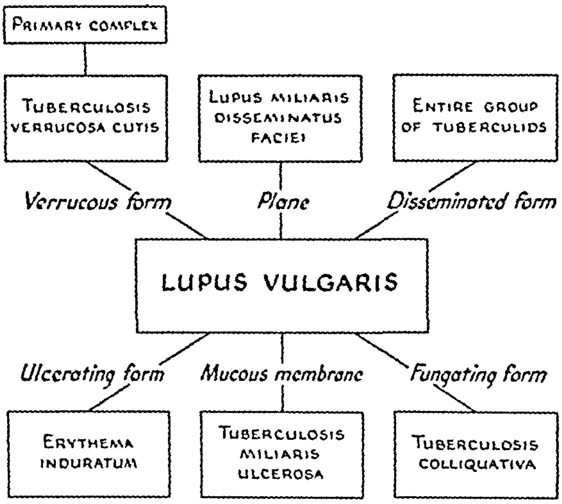
Without further description, it may readily be realized that lupus vulgaris may be a rather benign torpid process, involving only a small area, or it may be very destructive and widely disseminated. It is a disease of great variations and extremes, but one common characteristic for all types is the chronicity. Rate of growth of the lesions may be rather rapid, but usually they take months or even years to spread. There is no way of anticipating what may take place. In some patients the disease may seem to be controlled rather well when suddenly new lesions appear or new areas become involved. There is some seasonal incidence or recrudescence, late winter being the time when this tendency is most often noticed.

Lupus vulgaris may appear on any part of the body, but the face is certainly an area of predilection. Strangely the scalp is rarely involved, and if so only as an extension of facial occurrence. Why the face is more often invaded than any other part of the body is not known, but the frequent localization about the nose has led some to state that such involvement is secondary to a diseased nasal mucous membrane. Often the nasal mucosa, as well as the nasal openings and the structure of the nose, take part in the process, which may go on to destruction of the soft parts, with resulting unsightly deformity. It is the common involvement of the nose and face which makes lupus vulgaris such a hideous and terrifying disease, and ostracizes the patient in his social and economic life.

For each part of the body, lupus has certain more or less characteristic forms, but they are not of diagnostic importance. It must also be mentioned that the disease may occur with a number of disseminated lesions appearing simultaneously. This type is seen in childhood and may follow some acute infection, such as measles or scarlet fever. A variant of this disseminated type is the much more dangerous widely dispersed hemorrhagic postexanthematous eruption, which is more accurately a form of acute miliary tuberculosis than of lupus vulgaris.

The histologic picture of lupus vulgaris is almost as complex as its clinical manifestations. The predominating picture is that of a tuberculous granuloma, but many different combinations of the component parts of such an inflammation may be seen. The presence of groups of epithelioid tubercles, with giant cells set off from each other by lymphocytic infiltrates, is, in brief, what is seen. Caseation as seen in other organs is rare, but certain degrees of necrosis in the center of the tubercle is often noted. The inflammation begins high in the cutis and may spread laterally or even downward, but lupus vulgaris is usually rather superficial. The granuloma has sharp boundaries, appearing at times to have a capsule, but this is not the case. Blood vessels may be found in the granuloma, and remnants of such vessels make one believe that the inflammation followed the blood vessel network. Connective tissues and appendages are destroyed, and the epidermis may undergo a variety of changes, ranging from hypertrophy with acanthosis to complete destruction with ulceration. Remnants of epithelial cells may often be seen in the infiltrate, and this fact has been used as an explanation for the ease with which these cells may take on abnormal growth and cause epitheliomas to develop. The tendency to sclerosis is often developed in lupus tissue; thus an effort at healing is initiated. It must be emphasized that a great many different pictures may be seen microscopically from excised lupous tissue and that there is no pathognomonic observation. Tuberculosis may be observed microscopically in the lesion, but definite microscopic diagnosis of lupus vulgaris is most difficult.

From this brief clinical and histologic description, it may readily be realized that lupus vulgaris is a protean disease, but if one recalls the various forms and transitions this disease may undergo, one may much better understand all forms of cutaneous tuberculosis. In fact, there is hardly a known form of tuberculoderm that has not a prototype in lupus vulgaris. The scheme presented herein illustrates how lupus vulgaris may be taken as the common form to which all types of cutaneous tuberculosis may be compared.



PRIMARY COMPLEX
TUBERCULOSIS VERRUCOSA CUTIS
LUPUS MILIARIS DISSEMINATUS FACIEI
ENTIRE GROUP OF TUBERCULIDS
Verrucous form
Plane
Disseminated form
LUPUS VULGARIS
Ulcerating form
Mucous membrane
Fungating form
ERYTHEMA INDURATUM
TUBERCULOSIS MILIARIS ULCEROSA
TUBERCULOSIS COLLIQUATIVA

Schematic representation of relationship of lupus vulgaris and other types of cutaneous tuberculosis.

The criteria for the diagnosis of lupus vulgaris are:

1. Insidious onset
2. Primary lesion: the lupus nodule
3. Peripheral local extension
4. Gradual metamorphosis, assuming a type
5. Very slow growth
6. Topography—face, commonest location
7. Microscopic analysis: varied but tuberculoid structure present
8. Tuberculin reaction usually positive

One should search for internal tuberculosis especially in the lungs and glands; tubercle bacilli should be searched for by all known methods.

LUPUS MILIARIS DISSEMINATUS

Lupus miliaris disseminatus faciei occupies a unique position among the tuberculoderms. It possesses characteristics of both plane lupus vulgaris and of the facial type of tuberculid which is often called acnitis. It is a relatively rare disease, but, because of its similarity to the now popular rosacea-like tuberculid and to the miliary form of cutaneous sarcoid, it is worthy of considerable attention.

The eruption occurs almost exclusively on the face and even there shows a predilection for the eyelids, the upper lip, the chin and immediately adjacent areas. It rarely involves the forehead, ears or scalp. It has been seen on the neck. The rest of the body, even the elbow region and the fingers or the toes which are often the seat of tuberculids, is entirely free.

Onset is rather sudden but insidious, the lesions appearing painlessly and either individually or many at the same time, their number gradually increasing until the total number that are going to constitute the eruption have made their appearance. This may take up to six weeks. The total having been attained, no new lesions form. The body apparently is able to limit and control the outbreak to a comparatively few lesions; about fifty is the maximum. The individual lesion is small, but there is some variation in size, from that of a grain of wheat to a small pea. They remain discrete and do not coalesce to make a plaque, are symmetric, have the characteristic color of lupus nodules, are soft and are not covered with a crust. Occasionally the center appears to be pustular but on incision does not drain. The border is so sharp that the lesion can be destroyed with a microcautery. The lesions remain in situ for a varying length of time, from three to six months or even longer, and then gradually disappear, often leaving a variola-like scar. I have not seen recurrence in a single patient with lupus miliaris. The tuberculin reaction may or may not be positive. While much importance has been attached to a negative reaction, it has no bearing on the diagnosis.

The observation of a tubercle located just below the epidermis and having central caseous necrosis has been described so often that one expects always to find just that on microscopic examination, but that has not been my experience. I have seen considerable variation, sometimes the picture just described and at other times an epithelioid tubercle or a sharply circumscribed mass of tuberculoid structure with or without necrosis. The location may or may not be perifollicular.

The condition resembles lupus vulgaris because the indivdual lesion resembles a lupus nodule, has the same color and is similar under glass pressure and because of the histologic observations, which show it to be tuberculoid or even entirely like tuberculosis elsewhere in the body. It simulates the tuberculids because of its sudden exanthem-like appearance, its spontaneous disappearance with characteristic scarring and the great difficulty in demonstrating tubercle bacilli.

The criteria for diagnosis are:

1. Sudden appearance
2. Particular areas of the face only involved
3. Discrete lupus nodule-like lesion
4. Microscopic section
5. Indolent course
6. Self limited
7. Tuberculin reaction

Lupus miliaris disseminatus faciei might well be an abortive form of plane lupus vulgaris. The individual lesion cannot be differentiated from a lupus vulgaris nodule. However, the fact that the lesions remain discrete, without forming a plaque, and disappear spontaneously makes the condition different from ordinary lupus vulgaris. Treatment as a rule is not necessary. Vitamin D was administered to 2 patients with the condition without any apparent effect.

TUBERCULOSIS VERRUCOSA CUTIS

This form of cutaneous tuberculosis also is rare, and, although often considered in differential diagnoses, it occurs with such infrequency that its characteristics are not as well known as one would think. Just as I consider lupus miliaris closely related to plane lupus vulgaris, so do I consider tuberculosis verrucosa cutis as a mild benign form of verrucous lupus vulgaris. The condition has been observed often enough in pathologists, veterinarians and butchers to be looked on as an occupational disease and, because the infection is external, as a form of inoculation tuberculosis.

The initial lesion, its evolution and course, the lack of lupus nodules and the location readily differentiate the early process from verrucous lupus vulgaris, while in the well developed large plaque the differences are not so apparent.

The condition occurs almost exclusively on the hands, occasionally on the feet, but almost never elsewhere on the body. The particular regions are the periungual areas and over the knuckles and the thenar eminences. The initial lesion may resemble a torpid phlegmon, and, when seen as such, the evolution cannot be predicted. Most commonly it begins as a deep seated rather ill defined bluish red node. Scales form early, and the lesion enlarges and tends to exhibit zones, the central portion becoming soft and even pustular, encircled by a warty ring and outside of this a halo of dusky red inflammation which fades off into the surrounding skin. The degree of verrucosity varies a great deal, as do the other elements, depending on the size, rate of growth and location of the lesion.

Patients in whom tuberculosis verrucosa cutis develops have had tuberculosis previously and are therefore in a state of allergy; otherwise a positive reaction to inoculation would in all likelihood bring about a different type of lesion—a primary complex; since the verrucous type of tuberculosis of the skin is so benign, the patients also have a high degree of resistance. The disease occurs oftenest in adult men and rarely in children.

The lesion progresses in a centrifugal manner, which results in an annular or, at times, serpiginous lesion. Having attained a certain size, the lesion becomes stationary, and further changes occur only within the lesion. The center sinks, some scarring takes place and activity is noted at the borders and in a few islands within the lesion. The warty elevations vary somewhat in height and breadth, and there often is some crusting because of coagulated secretion. At times the lesion becomes converted into a thin scar, with activity confined to the periphery. Ascending lymphangitis and tuberculous adenitis of the adjacent nodes are possible complications, and, just as lymph stasis may occur in certain cases of lupus vulgaris, it may be noticed in patients with tuberculosis verrucosa cutis, the part becoming boggy and enlarged. The condition is chronic, and although it becomes stationary there is an effort on the part of the body to heal the lesion by scar formation; it does not heal spontaneously and may remain active for a long period; on the other hand, the lesions respond well to properly directed treatment. Roentgen therapy or some form of coagulative destruction are the treatments most often recommended.

The histologic observations are at times confusing because of the presence of acute or chronic inflammatory elements superimposed about areas of tuberculoid structure. Hyperkeratosis and a tuberculous type of tuberculoid structure must be present to permit one to diagnose the condition microscopically. At times the tuberculous infiltrate predominates, with few other elements present, while in other sections it is only with difficulty that one finds small areas of tuberculoid structure. Occasionally small areas of tuberculoid structure are entirely encircled by the hyperkeratotic epidermis. The degree of hyperkeratosis may be great, even forming horny cysts, but without some degree of hyperkeratosis a diagnosis of tuberculosis verrucosa cutis is not tenable. Caseous necrosis is absent.

The condition is relatively benign, but the danger of extension to the lymphatics must be kept in mind.

The criteria for diagnosis are:

1. Occurrence principally on the hands
2. Slow development after history of certain types of injury
3. Consideration of the occupation of the patient (physician, veterinarian, butcher)
4. Verrucous lesion
5. Microscopic section (difficult diagnosis)
6. Demonstrate tubercle bacilli by smear or animal inoculation
7. Tuberculin reaction

One should search for tuberculosis.

THE TUBERCULIDS

The existence of any of the tuberculids is based on an assumption that at some moment in the life of a person infected with tuberculosis, the bacilli became labile and reached the skin, which having become sensitized, reacted to the presence of the bacilli to a pronounced degree, thereby producing a lesion. The lesion is dependent on the state of allergy, the number and virulence of the organisms and possibly the depth and size of the blood vessels where the bacilli are lodged at the time the "id" reaction takes place. It is also assumed, and with considerable good evidence, that the bacilli are killed by the "id" reaction, so that the lesion is the result of the energetic tissue response and not due to continued growth of the bacilli. Hence tuberculids are individual lesions and do not extend contiguously; they tend to heal in a rather short time, and because of the intensity of the reaction, with resultant necrosis, they usually heal with a scar.

In order to comprehend the production of tuberculids, one must understand the immunobiologic aspects of tuberculosis as accepted today. All tuberculids are probably hematoembolic processes. The resulting morphologic lesion depends on many factors, but the anatomic location, both minute and regional, must play an important role in the appearance of the clinical lesion. I shall not review the well known facts concerning tissue reactions to the tubercle bacillus, for here we are concerned only with the diagnosis of the resulting cutaneous lesions. It is desirable, however, to view every tuberculid as a new inoculation, for the lesion to some degree approximates the second inoculation type of lesion seen in experimental tuberculosis. It is difficult to understand why tuberculids develop in a patient who has a subclinical or clinical type of systemic tuberculosis. What controls the time of onset? Why does the sowing of bacilli cease? Why are certain areas of the body so commonly involved while other parts are almost never the seat of a lesion? Is the bacillemia constantly present, or is it transitory? There are so many perplexing problems connected with the pathogenesis of the tuberculid that we can only accept what little evidence has been advanced and wait for further developments.

The tuberculids comprise a group of clinical conditions and therefore have had many different names applied to each type. It would simplify our understanding of the tuberculids if we would realize that they are all papular lesions, varying in size and in secondary changes. Since there is a surprising monomorphism in individual cases, mixtures of types, for example, lichen scrofulosorum (squamous papular tuberculid) and acnitis (necrotic papular tuberculid), are rarely seen; the conditions which predispose to a certain variety must be fairly well fixed even if we do not know what they are.

The microscopic appearance of a tuberculid is dependent on two factors: (1) the specific tissue response and (2) the secondary changes. Initially, there must be the reaction against the tubercle bacillus that one expects in an allergic subject (he must be allergic if one adheres to the theory of hematogenous sowing from an established internal focus), for infection with tubercle bacilli confers on a subject a property which the organism did not possess prior to the infection. This property, which is called allergy, increases the reactivity to subsequent infection or inoculation. The degree of allergy varies. It may be weak or strong or may even disappear, but of all species subject to infection with tubercle bacilli, I know of no species in which the reaction is so intense or so lasting as it is in human beings. Thus, although the tissue response will vary, it will follow the general pattern of tissue response against tuberculosis and will eventually result in tuberculoid structure. In some tuberculids, such as the scaling lichenoid type, that is all that will be found, the secondary change being only a mild scaling, but in the larger more intense legions, like the necrotic papular tuberculids, the central portion of the reaction in the lesion is so great that necrosis results, producing a core about which tuberculoid structure is found. Hence, in the necrotic tuberculids, the two elements—one specific and the other secondary—are to looked for. The microscopic diagnosis of tuberculids is difficult. Many diverse morphologic combinations may be found, but tuberculoid structure, preferably of the kind seen in tuberculosis, must be present in order for one to venture the diagnosis of tuberculid.

Just as the microscopic picture varies, so does the clinical appearance of the different kinds of tuberculids. It is not necessary to review the appearance of particular types of tuberculids, but it should be emphasized that on the pathogenesis rest certain common properties. As to be expected, the onset is rather sudden and may be exanthem-like. The lesions are usually symmetric because of the blood-borne invader. The lesions being small and superficial, they provoke practically no subjective symptoms. Because of their evolution, the lesions go through a cycle, the more torpid ones remaining papular, the more intense necrosing early. Scars often result, but some tuberculids may disappear without leaving a trace. The necrotic papular tuberculids often recur. It would therefore seem logical that the body conditions which permit the development of necrotic papular tuberculids must be similar to those which permit erythema induratum to develop. In both conditions there is often recurrence over a period of many years. Tuberculids which do not necrose apparently rarely recur, for example, lichen scrofulosorum (scaling papular tuberculid).

In summary, tuberculids occur because the infected body reacts against fresh implantations in an intense but effective manner, and the resulting lesions are more or less self limited as to size and duration. The type produced depends on many factors which one can hardly conjecture about, let alone prove.

The criteria for the diagnosis of the tuberculids may be applied to all types. They are:

1. Rather sudden onset
2. Symmetry
3. Fairly rapid evolution
4. Self-limited course
5. Areas of predilection for each type
6. Tuberculin reaction usually positive
7. Microscopic evidence of tuberculosis

A search for tuberculosis should be made.

SUMMARY

It should constantly be borne in mind that tuberculosis of the skin is the result of an integumentary reaction against infection with a specific organism and that the facts which have been accumulated about tuberculosis in general may be applied in a somewhat restricted manner to tuberculosis of the skin.

Because the morphologic entities which are now looked on as tuberculoderms were discovered and described individually and were included in the general category of tuberculosis long after their initial recognition, it is easily understood why they have been treated as entities rather than members of a group. This has resulted in a vast descriptive literature, in redundant minute differentiations and in a virtual neglect of the most important fact that tuberculosis of the skin is only a form of tuberculosis; just as tuberculosis in other organs produces a variety of clinical types, so does it also in the skin.

One must constantly keep in mind the hard gleaned facts about tuberculous infection. One must constantly contemplate the changing picture of the tissue response, and one must appreciate that the reaction of the human organism against the tubercle bacillus is discontinuous, so that the degree of resistance, and possibly immunity and allergy, is constantly changing. If a subject is going to be the victim of cutaneous tuberculosis, the particular type of lesion probably is dependent on the precise moment of the phase in the battle between the invader and the host when inception of the lesion takes place. Since the resulting lesions are diverse, both as to type and course, it seems best to continue to apply designating names rather than to use an over-all term, but one must not forget that one is dealing with tuberculosis.

PENICILLIN TREATMENT OF SUBACUTE BACTERIAL ENDOCARDITIS

Report of Eighteen Consecutive Cases

ALBERT C. HERRING, M.D.
and
WILLIAM M. DAVIS, M.D.
New York

Prior to the use of chemotherapeutic agents, subacute bacterial endocarditis was rarely if ever cured. With the increasing use of sulfonamide compounds in the treatment of this condition, series of cases were reported in which apparent cures were achieved in approximately 5 per cent of patients treated.[1] Recent experience with penicillin in a number of well substantiated series[2] indicates that the percentage of patients cured is substantially higher than among patients treated with sulfonamide compounds. It is the purpose of this communication to show the results of penicillin therapy in 18 consecutive cases of subacute bacterial endocarditis.

CLINICAL DATA

Selection of Cases.—In the two year period from Jan. 1, 1944 to Dec. 31, 1945, 18 patients with subacute bacterial endocarditis were admitted to St. Luke's Hospital. The diagnosis was established in each instance by the clinical history, physical findings and repeated positive blood cultures.

Table 1 shows the clinical data in the series of patients.

Age and Sex.—Ten patients in this series were males and 8 patients were females. Their ages varied from 6 to 77 years. The average age of patients in this series was 39.2 years.

Primary Cardiac Disease.—Three patients had congenital cardiac defects. Eleven patients had underlying rheumatic heart disease. Underlying arteriosclerotic heart disease was present in 2 cases. In 2 cases the etiology of the underlying cardiac lesion was not determined.

Infecting Organism.—In 16 cases the organism isolated was the Streptococcus viridans. In 1 case an undifferentiated streptococcus was revealed. In 1 case a pleomorphic streptococcus was found.

Duration of Infection.—The apparent duration of infection in each case varied between three weeks and seven months. It is of interest to note that failures and deaths occurred in cases in which infection had existed longer than six weeks. Yet in 2 cases an infection of at least five months' duration was arrested.

Penicillin Sensitivity.—The recovered organism was tested in 17 cases for its sensitivity to penicillin in various dilutions. The method used was a serial dilution technic used at the Brooklyn Jewish Hospital. The original sensitivities varied between 0.008 and 0.15 unit per cubic centimeter. The response to treatment could not be predicted from the original sensitivity of the organism. Failures occurred in those cases in which the penicillin sensitivity was more than 0.03 unit per cubic centimeter. In 3 patients who relapsed there was a gradual increase in the resistance of the organism.

Penicillin Blood Levels.—During the course of therapy, penicillin serum levels were determined in 15 patients, and these were used to gage the adequacy of penicillin dosage. It was our aim to maintain the serum concentration well above the sensitivity of the isolated organism, preferably five to ten times the level required to inhibit the organism's growth in vitro.

Method of Administration, Dosage and Duration of Penicillin Therapy.—The usual method of administration of penicillin was by continuous intravenous infusion. The daily dosage was dissolved in 1,000 cc. of isotonic sodium chloride solution and the drip regulated to deliver this volume in twenty-four hours. By refinement of intravenous technic, new short 23 gage needles being used, the veins of the hand and forearm were utilized. The arm was splinted below the elbow with individually fitted padded plaster half casts. Such an arrangement is comfortable and allows movement of elbow and shoulder. In certain cases the development of congestive heart failure necessitated the use of 5 per cent dextrose solution in distilled water as the vehicle. The most annoying obstacle to the use of intravenous administration has been frequent local thrombophlebitis at the site of venipuncture.

This was partially reduced by changing arms every three to four days. In some cases the concomitant

---

From the Medical Service, St. Luke's Hospital.

Dr. Herring is attending physician, Medical Service, and Dr. Davis is former resident physician, Medical Service.

Because of lack of space this article is abbreviated in THE JOURNAL by the omission of 3 of the 5 reports of cases originally included.

* The organism in case 7 was an undifferentiated streptococcus and in case 18 was a pleomorphic streptococcus. In the other 16 cases it was Streptococcus viridans.

** Congenital heart disease.

† Continuous intravenous infusion.

‡ Rheumatic heart disease

§ Interrupted intramuscular injection.

¶ Arteriosclerotic heart disease.

‖ Continuous intramuscular infusion.

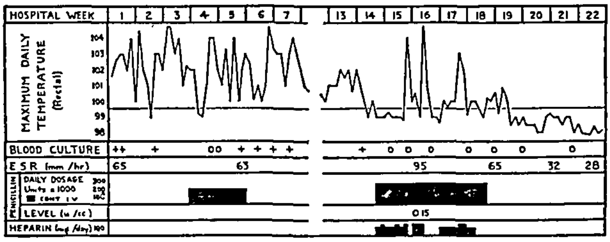
use of heparin appeared to decrease local thrombophlebitis.

Continuous intramuscular drip was used for the entire period of treatment of 5 patients with excellent results. It was also used for variable periods in 4 other patients. The daily volume of sodium chloride solution with intramuscular drip was 500 to 1,000 cc. In some cases there were considerable local reactions at the needle site. This difficulty was more frequent and severe with large doses of penicillin.

Interrupted intramuscular injections of penicillin were used for short periods of time in patients in whom the continuous intravenous or intramuscular drip had to be discontinued temporarily.

A four week course of penicillin was given in the majority of cases. The daily dosage of penicillin varied from 200,000 to 500,000 units. With patients who relapsed much larger doses were given in longer courses. The total amount of penicillin administered to any single patient ranged between 2,800,000 and 1,114,020,000 units.

Heparin.—Heparin was used in 9 patients. In 4 patients it was employed throughout a successful course of penicillin. In 3 patients heparin was employed during only part of a course. In case 9 it was used during a first unsuccessful course of treatment and omitted during a second successful course. In case 18, heparin was administered during several of the patient's multiple courses of penicillin.



This illustrates failure with one short course of treatment followed by successful arrest of infection with a four week course of penicillin. This patient was again treated successfully twenty months later for a second episode of subacute bacterial endocarditis which was apparently a reinfection. (Case 1).

The daily dose of heparin varied between 50 and 250 mg. It was incorporated in the penicillin infusion. The coagulation time was determined at least once daily by the Lee-White method and was kept between thirty and sixty seconds by varying the dosage. In case 18 heparin was also used in small doses for local anticoagulant effect in an effort to avert local thrombophlebitis at the site of intravenous administration of large doses of penicillin. No hemorrhagic phenomena attributable to heparin were noted. Three patients had febrile and systemic reactions of a sensitivity type which seemed to be due to heparin.

SUMMARIES OF CASES

Two representative case summaries from the series are presented.

Case 1 (the chart).—W. H., a man aged 27 years with a known heart murmur since the age of 7, enjoyed excellent health until eight months prior to admission, when he had left-sided pleurisy for two weeks. Three months later he left work because of increasing fatigue, followed by anorexia, general malaise, loss of weight, night sweats and fever.

On admission, March 9, 1944, he was acutely ill, with pallor and anemia, clubbed fingers, palpable spleen and temperature of 101.4 F. The heart percussed in the right thorax with the apex impulse in the fifth right interspace 1 cm. beyond the midclavicular line. There was a harsh systolic thrill and murmur over the base of the heart just to the left of the sternum.

Angiographic studies with intravenous iodopyracet injection showed a dextroplaced heart, an interauricular septal defect, pronounced dilatation of the pulmonary arteries, but no transposition of the cardiac chambers.

The patient ran a spiking temperature to as high as 105 F., and three blood cultures were positive for S. viridans. March 28, continuous intravenous infusion of 200,000 units of penicillin daily was started. On the second day of therapy a pulmonary infarct occurred. Temperature continued to be elevated during treatment. Penicillin could be administered for only two weeks because limited supplies were available at that time. Blood cultures taken the last day of treatment and subsequent culture grew S. viridans.

During the next six weeks the patient continued to be acutely ill with fever, a second pulmonary infarct and cardiac enlargement. The sensitivity to penicillin of the organism recovered from blood culture was found to be 0.047 unit per cubic centimeter. June 12 penicillin was resumed in a daily dosage of 250,000 units by continuous infusion. Heparin was also given in dosage of 100 to 150 mg. daily. Penicillin was continued for twenty-eight days, and the patient received a course of 7,000,000 units.

The patient's temperature was normal from the second day of treatment on, except for several spikes to 104 and 105 F. Difficulty was experienced in obtaining the same brand of heparin for this patient, and the fever may have been caused by the use of the product of several different manufacturers. Blood cultures taken during treatment and all subsequent cultures were negative. The patient had an uneventful convalescence.

The patient returned to full time work and was in good health for the next twenty months. He attended clinic regularly. In May 1946, he entered the clinic with a two month history of weight loss and fatigue. Blood culture was found to be positive May 28.

On admission June 1 the patient appeared moderately well. The cardiac findings were unchanged since the previous admission. The spleen tip was palpable.

The patient had a low grade fever and blood cultures grew S. viridans, the penicillin sensitivity of which was 0.125 unit per cubic centimeter. June 3 the continuous intravenous administration of 5,000,000 units of penicillin with 50 mg. of heparin was started and continued for thirty-seven days. Blood cultures taken June 17 was positive after ten days of incubation. Other blood cultures were negative and the patient's course was uneventful. He received a total of 185,000,000 units of penicillin.

Since discharge the patient has remained in good health. Blood cultures have been negative. He has been followed five months.

Case 18.—M. S., a groceryman aged 47, had several previous admissions to this hospital for herniorrhaphy, hydrocelectomy and left nephrectomy for chronic hydronephrosis. There was no history of cardiac disease, although a harsh apical systolic murmur was noted on the last admission in 1941. Six weeks before admission the patient experienced pain in the left hip and shoulders accompanied by mild anorexia, loss of weight and malaise.

Examination on admission, Nov. 26, 1945, revealed a thin, chronically ill man with marked scoliotic deformity of the thoracic portion of the spine. The heart was enlarged and there was a harsh loud apical systolic murmur, widely transmitted.

The patient ran a swinging temperature, and five blood cultures were positive for a pleomorphic streptococcus. The organism failed to grow well on solid mediums, and sensitivity studies indicated that it was one half as sensitive to penicillin as the control strain (0.008 unit per cubic centimeter).

On December 8, the continuous intravenous infusion of 400,000 units of penicillin daily was started; it was continued for five weeks. An additional week of interrupted intramuscular doses of penicillin was given. During this week, blood cultures were again positive. Penicillin was stopped. After one week the patient's temperature began to spike daily, and four additional blood cultures were positive. A total of 15,520,000 units of penicillin had been given and blood levels were between 0.05 and 0.75 unit per cubic centimeter.

On January 30, the daily administration of 500,000 units of penicillin was resumed by continuous intravenous drip. After one week this was increased to 1,000,000 units daily with blood level of 0.75 unit per cubic centimeter. At this time local thrombophlebitis developed in the arm veins, and temporarily a continuous intramuscular drip was used. Strong local muscular reaction appeared. The continuous intravenous drip was resumed and heparin was administered in daily 50 mg. doses. Penicillin level attained was 1 unit per cubic centimeter. March 11, penicillin was stopped; a total of 58,000,000 units had been given during the second six week course.

At this point the patient's general condition was good and the situation appeared favorable. However, blood cultures again grew the same pleomorphic streptococcus and sensitivity studies indicated a several fold increase in the organism's resistance to penicillin.

On March 28, penicillin was resumed; 4,000,000 units of penicillin and 100 mg. of heparin were given daily by continuous intravenous infusion. Heparin was then omitted, and because of dental infection all teeth were extracted. Penicillin varied between 0.8 and 3.3 units per cubic centimeter. It was continued for fifty-two days, to a total of 208,000,000 units.

Blood cultures again became positive, accompanied by fever. Dr. Leo Loewe of the Brooklyn Jewish Hospital saw the patient in consultation and because of the increasing penicillin resistance of the organism suggested much higher dosage.

On May 28, penicillin was started in dosage of 5,000,000 units daily with 50 mg. of heparin daily by continuous drip. Blood cultures continued to be positive, and on June 4 penicillin was increased to 10,000,000 units daily; it was continued for forty-two days. Penicillin levels ranged between 1.5 and 12 units per cubic centimeter, well above the concomitant organism sensitivities to penicillin of 0.06 and 0.15 unit per cubic centimeter. A total of 452,500,000 units of penicillin was given during this fourth course of therapy.

Dr. Loewe reported the organism to be the type of streptococcus "s.b.e.," which he has described and found extremely resistant to penicillin. At his suggestion streptomycin was obtained and started on July 20 in daily dosage of 2 Gm. by divided intramuscular injection. With completion of the course positive blood cultures again indicated relapse. The total streptomycin received was 42 Gm.

On August 18, a further two week course of streptomycin was started. The streptomycin was given intramuscularly in daily 2 Gm. dosage. Simultaneously, a continuous intravenous infusion of 10,000,000 units of penicillin was given daily. After ten days the penicillin dosage was increased to 20,000,000 units daily and maintained for two weeks. A total dosage of 28 Gm. of streptomycin and 380,000,000 units of penicillin had been given during this fifth course. Penicillin levels varied between 5 and 43 units per cubic centimeter.

The patient's general condition was good and he was allowed to be up and about. However, continuing positive blood cultures and fever indicated persistent infection. Further strenuous therapy was decided against. The patient was discharged home.

Six weeks later the patient was readmitted to the hospital with a history of weakness, anorexia, chills, fever and pains in shoulder and neck. He appeared chronically ill and emaciated. He showed fever, and blood cultures were positive. Sulfadiazine was administered in the usual dosage. In a stormy one month course the patient went downhill rapidly; he died Dec. 24, 1946. No autopsy was permitted.

RESULT OF TREATMENT

The results of treatment in these cases may be summarized as follows: Ten patients are alive and well; 7 patients have died, and 1 patient is in relapse. An analysis of the patients who died follows:

Patient 2 received only one short course of penicillin; no further penicillin could be obtained, and he died in relapse. Patient 9 died in the course of treatment with intramuscular doses of penicillin which were inadequate because of the scarcity of the drug.

Three patients died in the immediate post-therapeutic period. Patient 12 died in relapse after a four week course of therapy failed to arrest the infection. Patient 7 died the night of discharge from the hospital after overexertion and excessive drinking. No evidence of active infection was present at discharge. Patient 18 died after receiving five courses of penicillin in massive dosage and two courses of streptomycin.

Two patients died about one year after completion of treatment. Patient 3 was well for eleven months after treatment and died of a cerebrovascular accident. Patient 6 had severe rheumatic aortic and mitral valvular disease and died in congestive heart failure fifteen and one-half months after treatment. After the arrest of her infection, she had several episodes of rheumatic fever with persistent chronic congestive heart failure. Blood cultures were consistently negative.

Apparently penicillin arrested the infection in 3 patients who died. One of these patients died of an apparently unrelated cerebrovascular accident. Two patients had severely damaged hearts with marked aortic regurgitation.

The results of treatment are tabulated in table 2.

Table 2.—*Results of Treatment*

Total cases	18
Infection arrested	13
Relapse—infection uncontrolled	4
Death during treatment	1
Alive and well (one year or more)	10
Death after apparent termination of infection	3
Total deaths	7

We were able to control the infection in approximately 75 per cent of the cases in our series. The remaining 25 per cent were treatment failures who died during the course of therapy or patients whose infecting organism proved resistant to penicillin. Among the 75 per cent in whom the infection was controlled there were 3 subsequent deaths. In our series 10 patients, or 55 per cent of the original series, are alive and well after a year or more.

Case 1 is of particular interest. This patient recovered from a first illness and was well for twenty months. Then for the second time typical manifestations of subacute bacterial endocarditis developed. Streptococcus viridans was recovered from the blood. He was treated successfully and has been well for five months.

COMMENT

A comparison of the results of treatment in our series with those of other clinics indicates that they are similar.[2] Approximately 25 per cent treatment failures are reported by most observers. This figure appears difficult to reduce. It is questionable whether the fatal embolic phenomena that occur can be averted. They appear to be no less frequent in heparin-treated patients. The cardiac complications that occur during treatment, such as congestive heart failures and arrhythmias, can be minimized if promptly recognized and treated. The hope for improving the number of cures appears to be in the recognition of those cases the organism in which has an initial high resistance to penicillin and which will require massive doses of penicillin. The recent report of Loewe[3] concerning the isolation of a penicillin-resistant streptococcus which he has called

---

3. Loewe, L.; Plummer, N.; Niven, C. F., Jr., and Sherman, J. M.: Streptococcus s.b.e. in Subacute Bacterial Endocarditis, J. A. M. A. 130: 257 (Feb. 2) 1946.

"streptococcus s.b.e." is of interest. The fact that during treatment the recovered organism frequently shows increasing resistance to penicillin indicates the need for an initial dosage of penicillin which is sufficiently high to assure effectiveness. In our series failures occurred in those patients whose organisms showed a penicillin sensitivity of more than 0.03 unit per cubic centimeter. Several patients responded satisfactorily although their organisms showed penicillin sensitivities greater than this figure.

During the therapeutic course of penicillin it is difficult to judge the effectiveness of treatment. During the administration of penicillin, negative blood cultures and other signs of clinical improvement are usual. Persisting fever and elevated sedimentation rate may not be unfavorable signs, since both can be caused by many factors other than persistent infection. The only method of judging the effectiveness of treatment is a period of observation at the end of a course of penicillin. In cases in which relapse occurred, signs of relapse and positive blood cultures appeared within the initial two week period following cessation of therapy.

Most patients will apparently respond to a daily dosage of 500,000 units of penicillin. However, because the in vitro sensitivity of the organism does not give an accurate measure of the in vivo bactericidal level, much larger doses are recommended. We believe all patients should receive at least 2,000,000 units of penicillin daily in a six week course. If the penicillin sensitivity is greater than 0.06 unit per cubic centimeter, daily doses of 5,000,000 units or more are indicated at the onset.

We cannot recommend the routine use of combined penicillin and heparin treatment. In this small series the results were inconclusive and failed to show any definite benefit from the use of heparin. In view of the difficulties of administration and the possible dangers of heparin, it has been used recently for two purposes. It has been used in cases of extremely resistant disease as an additional, possibly beneficial measure when previous courses of penicillin have failed. It has also been used in small doses for its local anticoagulant effect to prevent thrombophlebitis when large doses of penicillin were being given intravenously.

The method of administration of penicillin is much discussed. From the reported series, it is apparent that the different methods used give much the same degree of success. Our familiarity with the continuous intravenous technic leads us to favor it. The continuous intramuscular drip appears to be equally effective in our hands.

SUMMARY

A series of 18 cases of subacute bacterial endocarditis treated with penicillin is reported. In 13 of the patients the infection was arrested. Ten of the patients are alive and have been well over a period of at least a year. The results of treatment and failures are discussed.

A patient who has recovered satisfactorily from two separate episodes of subacute bacterial endocarditis separated by twenty months of apparent good health is reported.

The use of 2,000,000 units of penicillin daily in all cases is recommended. In patients with more resistant organisms doses of 5,000,000 units or more of penicillin should be used.

The administration of penicillin by continuous intravenous or intramuscular drip is recommended.

The combined use of penicillin and heparin offers no definite benefits and is not recommended.

CURRENT PHARMACOLOGY

General Principles in Practical Clinical Application

CHAUNCEY D. LEAKE, Ph.D.
Galveston, Texas

In acquiring more precise pharmacologic knowledge about chemicals used in medicine, the alert physician is able more satisfactorily to apply such information for the benefit of his patients, whether in the diagnosis, prevention or treatment of disease. In spite of the great numbers of useful new drugs being introduced into medicine for various purposes, the most important development of current pharmacology is theoretical, in connection with the establishment of general principles. An acquaintance with general principles of pharmacology, especially as developed by Clark,[1] is being recognized as increasingly helpful in the practical clinical use of drugs.

It may seem peculiar to the hard-headed clinician not to offer any specific information in this discussion about any particular drug. He may ask what value it is to him in trying to help his patients to have some general ideas about time-concentration relationships, since what he wants to know is how much of which drug to use when. The answer is that knowledge of the general principles of pharmacology aids in the choice and most efficient use of chemicals appropriate for the particular clinical situation with which he may be concerned. It is of practical help in judging the use of drugs to understand the factors involved in the intensity of drug action, to know something of the general principles of dose-effect and time-concentration relationships and to realize something of the mechanisms of drug action. While new terminology in technical matters may be strange and confusing at first, the direct intellectual effort put into its comprehension will aid greatly in its effective use. The intelligent grasp of the general principles of current pharmacology and of the basic concepts involved will promote more intelligent, more effective and more economical use of drugs, with greater satisfaction for patient and physician.

Thousands of chemicals are available for clinical use. New drugs are continually being developed and exploited. While crude drugs, comprising uncontrolled chemical mixtures from natural sources, are diminishing in number and importance, new synthetic chemicals for medical use are increasing in quantity and value. Frequently the clinical use of drugs is not satisfactorily established on the basis of demonstrable biologic action. Physicians are often fooled over claims made for drugs. An understanding of a few simple general principles regarding the appraisal of drugs will help the average physician to judge for himself the value of data offered him by the well coached detail men who try to persuade him to use new drugs in which there may be large commercial interest.

It is difficult to attempt to derive general principles regarding drug action from the vast amount of detailed knowledge and opinion which has accumulated for individual drugs. Nevertheless such generalities may be highly significant for the intelligent physician

in evaluating drug action and in determining the indications for appropriate drug use. Such principles may offer the discriminating physician reliable guides for judgment and choice of regimen in clinical situations in which chemicals may help.

THE DEVELOPMENT OF PHARMACOLOGY

Pharmacology is the study of the action of chemicals on living things. The action may be beneficial or harmful, and the living things may be plant or animal. Pharmacology is thus a broad scientific discipline. It is chiefly applied in medicine. However, other applications are rapidly developing in agriculture, industrial hygiene, law and even in sociology. Pharmacology is closely related to other scientific disciplines, such as biochemistry, biophysics, physiology, microbiology, pathology and pharmaceutic chemistry.[2]

It is necessary to differentiate the study of the action of drugs from the proposition of the practical use of drugs in medicine. The process of acquiring verifiable and agreed-on knowledge of the action of chemicals on living things is a scientific matter. The application of this knowledge to the benefit of a particular sick patient is an artistic venture, calling for the exercise of judgment, discrimination and choice. In modern medical teamwork science and art complement each other. When chemicals are concerned, the pharmacologists of the team represent science and are responsible for acquiring verifiable knowledge about the action of chemicals on living things, while the physicians on the team represent the art, and are responsible for the wise and judicious application of the knowledge available to accomplish benefit to the patient. To succeed, physicians must possess and appreciate the knowledge and understand the principles of its application.

Pharmacology began anciently with observations of the action of crude plant, animal and mineral materials when tried for food. Primitive and isolated peoples all over the world developed an elaborate folk lore regarding the application of such observations to disease. Most of these applications were sensible. Thus the Modoc Indians in Northern California observed that the eating of the bark of a certain tree produces purgation. They then rationally used this bark when constipated. The ancient Egyptians formulated their slowly acquired drug lore into recipe books, which recommended the use of various preparations in various clinical conditions.[3] These recipes were copied and expanded by the Greeks and Romans, frequently combined into complex prescriptions by Arabian and medieval physicians, and finally were subjected to increasingly careful analysis beginning with the rise of modern chemistry.

Modern pharamacology began in the eighteenth century with the establishment of chemistry on a quantitative basis. Crude drug mixtures could then be analyzed for their active principles. Serturner (1783-1841) in Germany isolated a sleep-producing crystalline material from opium which he called morphine, with reference to the Graeco-Roman god of sleep. This was followed by the isolation of many other alkaloids and, later, of other types of active principles, including those found in vitamins, hormones, antibiotics and even in biologic preparations for immunology.

Not satisfied with active chemical agents found in nature, pharmocologists began to try to improve on them, in order to increase the desired effect and reduce toxicity. The success with which this may be accomplished was first clearly shown in the many synthetic local anesthetics which are such an improvement over the naturally occurring cocaine. It is necessary first to identify the active principle chemically. Often this is an arduous job. But it has been successfully accomplished, even with such complex compounds as the alkaloids, steroids, hormones, vitamins and antibiotics. Now by slight chemical modification, it is possible to synthesize a considerable series of related compounds, in order to choose the one that is best suited for the particular purpose in mind.

The main criteria for the choice of a drug for a particular purpose are low toxicity, desired activity, prompt effect, easily controlled effect, no untoward reactions, even on frequently repeated administration, and ease of administration and manufacture.

DRUG STANDARDIZATION

In order to be certain of uniformity of clinical response to the same dose of a drug, it is necessary that the drug be standardized. This was recognized as long ago as the sixteenth century. Valerius Cordus (1515-1544) prepared a formulary for the use of the druggists of the city of Nuremberg. This was adopted by the senate of the city as the standard, to be followed by all druggists. This became then the first official pharmacopoeia.[4] The local physicians were now assured that the drugs they ordered by official name would be always the same, with unvarying characteristics. They could thus expect reasonable uniformity of effect from the same dosage of such standard preparations. The drug standards agreed on in pharmacopoeia are usually given legal support. In this country the Food and Drug Administration also protects the public from harm and exploitation in connection with new drugs.

When the active principles of crude drugs were isolated in chemically pure form, a great advance was possible in standardization, since now the crystalline material could be made to conform to specific chemical standards. A more precise relationship between dosage and effect thus became possible.

The American Medical Association at the beginning of the twentieth century established the Council on Pharmacy and Chemistry. This is composed of a group of experts who serve without remuneration. This Council examines the claims of all new drugs. It publishes annually "New and Nonofficial Remedies." To be included in "New and Nonofficial Remedies," a drug must meet certain minimum standards regarding identification, definiteness of action and restriction to reasonable claims, based on available evidence.

Physicians will find it helpful to give increasing attention to the "Pharmacopoeia of the United States" and to "New and Nonofficial Remedies." The "Pharmacopoeia of the United States" was first established in 1820 by a general convention of physicians, druggists and interested public officials. The Pharmacopoeia Convention meets regularly, and delegates are accepted from state and other medical societies. The pharmacopoeia guarantees, by legal support, that drugs offered under the name indicated in the pharmacopoeia must conform to the standards established in the pharmacopoeia. The Food and Drug Administration enforces its standards.

[4] Schelenz, H.: Geschichte der Pharmazie, Berlin, J. Springer, 1904

The full value of establishing drug standards in any political area depends on three factors, which physicians should be prepared to support: (1) agreement on what constitutes the standard of reference, (2) agreement on the definition of the drug and on adequate methods of estimating its purity and (3) agreement on enforcement of the standard. The important problem is to obtain agreement. Although difficult, agreement regarding drug standards has been achieved on an international level, and this may well be considered the major accomplishment of the League of Nations. The successful intelligent use of drugs is impossible without an appreciation of the importance of drug standardization.

The use of public names of drugs is important to the physician. It means much saving in money. A chemical agent sold under a "trade name" may cost ten times as much as the same drug sold under a public name. It is important for physicians to know the public names, if available, of proprietary drugs and to use such drugs under public names.[5] When physicians do a lot of dispensing it is economical to use drug names as listed in the pharmacopoeia and when using combinations of drugs to follow the formulas in "The National Formulary."

When new drugs are developed for medical use, there is a systematic way of appraising their value.[6] This should begin with an exhaustive study of toxicity on single and repeated dose. All phases of possible toxic action should be analyzed and described for the benefit of the physician. There should then be offered full information on rates and ways of absorption into the body. What happens to the drug in the body should be studied and described. The physicians should be informed regarding the rate of detoxification and the rate and mode of excretion. General and special pharmacologic properties should be described in detail. This information should be offered in comparison with related and commonly used chemicals offered for the same purpose. The physician is then in a reasonable position to judge for himself what may be the best drug, in a series of related compounds, for the particular purpose he has in mind. It is this sort of evidence that the physician should insist on receiving from commercial pharmaceutic concerns. He should be offered more straight information regarding what a drug does and how it acts than persuasive suggestions for what clinical conditions to use it. The physician's judgment should tell him for what purposes to use a drug. It is not the function of commercial pharmaceutic concerns to tell a physician how to practice medicine. It is their responsibility, however, to give the physician full scientific information regarding the drug they are interested in promoting.

When a drug has been thoroughly studied in a scientific manner, it may be ready for controlled clinical evaluation. In this it is essential to take into account the natural history of the particular diseased condition in which it is proposed to study the drug. The clinical investigator must estimate the healing power of nature in respect to the particular disease with which he is dealing. He must also beware of the logical fallacy of confusing sequence of events with cause and effect. If there is sound clinical evidence to support the scientific background of the drug, there may be justification for its inclusion in "New and Nonofficial Remedies" and its being offered to physicians for general clinical use. But physicians should insist always on having this information, and they should then appraise for themselves the evidence regarding the drug.

FACTORS MODIFYING DRUG ACTION

The chief factors modifying drug action are dosage, the ratio of the rate of absorption of the drug through the body to the rate of its destruction or excretion, the physical-chemical properties of the drug and the individual peculiarities of the particular patient to whom the drug is given. The relation of these factors to the intensity of drug action may be indicated by the shorthand formula:

$$I = (f)\, D\, \frac{rA}{rE}, P, S$$

where I is the intensity of drug action, D is dosage, rA is rate of absorption or distribution of the chemical through the living tissue involved, rE is the rate of excretion or removal of the drug from the living tissue concerned, P is the physico-chemical properties of the drug and S is the peculiar individual characteristics and sensitivities of the particular patient or living tissue concerned.

By dosage is meant mass of chemical per mass of body tissue excluding fat. This suggests the importance of dosage on the basis of milligrams of drug per kilogram of body weight. Many of the newer drugs are being introduced for use in this manner. Drugs with a more general and less toxic action may be given by "average dose," but for precise drug use it is wise to work out dosage in terms of milligrams per kilogram or in terms of millimol equivalents.

The mode of administration profoundly modifies dose effects. This is because the mode of administration is important in the rate of absorption of the drug. It is practically helpful for the physician to study technics of medication, in order to obtain the most satisfactory results with patients.[7] Absorption is slowest, of course, through the skin. It is next most rapid through the mucous membranes of the alimentary tract. It is important to remember the rectum as an absorbing area when it may be difficult to get satisfactory administration by mouth. Absorption of gaseous agents across the respiratory mucous membrane is very rapid. Intramuscular injection offers steady absorption for drugs in oil suspension. Parenteral administration, of course, requires aseptic precautions. Subcutaneous injection is not a particularly satisfactory method of administering drugs, but it is widely used. The most rapid distribution is obtained when a drug is given by vein. Sometimes a drug may be given into the spinal canal for particular local effects there. It is wise to remember that drugs may be absorbed from the mucous membranes of the vaginal tract, the ear or the eye.[8] Sometimes a drug given only for local effect at the point of application may be absorbed and produce a systemic reaction.

It is helpful to know something about the rate of drug destruction or excretion.[9] This gives the clue to the important problem of how frequently to repeat administration. Many drugs, such as penicillin or the sulfonamide compounds, are rapidly excreted in the urine and require frequent administration in order to maintain the concentration necessary for effectiveness. Many drugs are detoxified by combining with amino acids in the body. When this is possible, allergic effects may occur from the drug.[10] All drugs which have a ring structure chemically, with amino groups or phenolic hydroxyl groups, may combine with amino acids and thus give rise to allergic responses in sensitized tissue. Drugs such as aspirin, amidopyrine, the sulfonamide compounds, local anesthetics and aniline derivatives may combine readily with amino acids and produce allergic effects. A physician cannot tell which patient may show the allergic reaction or where, but he should be prepared to expect such reactions in at least 5 per cent of patients given such drugs.

Strenuous efforts are being made to delay the excretion of penicillin (by giving such agents as caronamide) or to decrease the rate of absorption (by use of procaine conjugates in oil), so as to prolong the effective concentration. When we know more about the chemical makeup of penicillin we may be able to devise chemical relatives which will be more slowly excreted and so give a more lasting effect.

The physical chemical properties of drugs are important with respect to their action in the body. If the drug is more soluble in oily material than in water, it will tend to concentrate in the oily parts of the body. Those of greatest functional importance are the elements of the nervous system. Thus, most drugs acting on the nervous system have a high oil-water solubility coefficient. The redox potentials of drugs, as well as their polarity properties, are important in respect to their reaction with enzyme systems in cells. These are matters which will become increasingly significant as we learn more about them, and physicians should be prepared to acquire this new knowledge as it develops.

Highly pertinent from the physician's standpoint is the estimation of the peculiarities of his individual patient with respect to drug reaction. Age, sex, metabolic state, constitutional factors and allergic tendencies must be appraised. Careful clinical judgment is required of the physician to evaluate those individual factors in his particular patient which may influence drug action. In general, the high metabolic rate of infants diminishes quickly to rise gradually to adolescence and to maintain a plateau until the fourth or fifth decade, when there is gradual decline. The estimation of metabolic status is a difficult clinical problem, but it is significant in connection with the activity of many different types of drugs. Some drugs, such as morphine, do not follow ordinary rules regarding age effects. Infants and old persons in general are more sensitive to morphine than persons in the prime of life. It is particularly important to appraise the autonomic nervous balance. Some persons may be peculiarly sensitive to sympathetic drugs, while others may show a higher sensitivity with respect to drugs acting on the parasympathetic system. Most important is the proposition of appraising allergic tendencies in a patient. This should always be investigated in order to avoid, if possible, allergic or other untoward reactions to drugs which may produce such undesired effects.

DOSE-EFFECT RELATIONSHIPS

Physicians must remember that different persons will respond differently to the same dose of the same drug.[11] This factor of individual variation in response to drugs can roughly be represented by "distribution curves" in which increasing intensity of reaction to the same dose is indicated along the horizontal axis, while the vertical axis shows the number of persons grouped with regard to the same intensity of reaction. In general there will be some persons who will show a relatively small response. The great majority will show the "average effect." A small number of persons may show a particularly intense reaction from a dose that might produce no effect in the less sensitive person.

When results are accumulated with reference to all or no effect (as cure or death), the curve is sigmoid and shows the percentage of persons reacting, when arranged on the vertical axis, to increasing dosage on the horizontal axis. Such curves are particularly important in the quantitative estimation of toxicity and effectiveness.

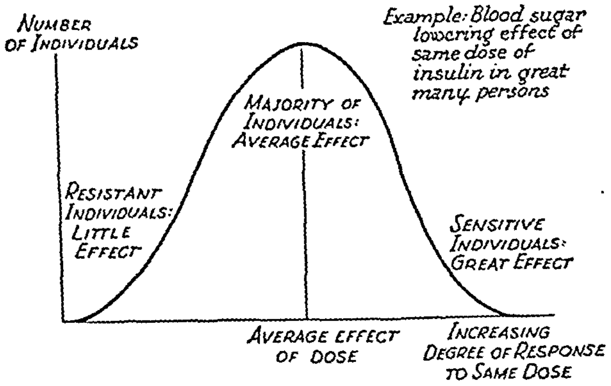

Fig. 1.—Relation of the number of reacting persons to graded response to the same dose of a drug (example: lowering effect of the same dose of insulin on the blood sugar in many persons).

Because of its ease of estimation under experimental conditions, the 50 per cent point on the curve is usually taken as the standard of reference. Thus, ED_{50} refers to the 50 per cent effective dose, that is, the dosage which will be effective, in the intensity desired, on 50 per cent of the organisms to which the drug is administered. In the same way LD_{50} refers to the dosage at which 50 per cent of the organisms to which the drug is administered may be expected to die. The ratio between the ED_{50} and the LD_{50} of a drug under standardized experimental conditions is sometimes referred to as the "safety index."

In applying this scientific knowledge, however, it is essential for the physician to remember that he is not interested in the dosage which will produce the desired effect in only 50 per cent of his patients, and he is certainly not interested in the dosage which may kill 50 per cent of his patients. The point is that the effective dose range of a drug may overlap the lethal range or the range of toxic reaction. This is the case, for example, with such drugs as emetine hydrochloride. Since the mechanisms of desired action and of death

may be different, the "slopes" of the curves may differ and overlap may readily occur. It is practically important for physicians to require pharmaceutic manufacturing houses to give precise information on the ED_{99} with relation to the LD_1, that is the ratio between the dosage which might be expected to produce the desired effect in practically all patients, to the dosage that might produce an untoward reaction in the most sensitive patient.[12]

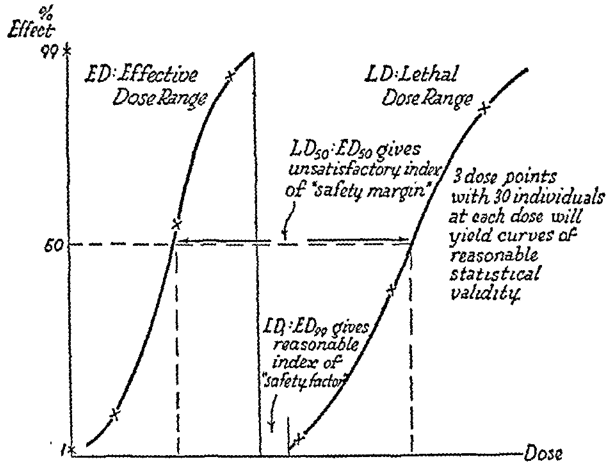

Fig. 2.—Relation of dose to percentage effect.

TIME-CONCENTRATION RELATIONSHIPS

Time is an unavoidable factor in the biologic response to drugs. For certain drugs, such as the inhalation anesthetics, the effective concentration for anesthesia, if maintained long enough, might produce untoward or even lethal effects. Accordingly, it is necessary to have data expressed in time-concentration curves. This may assist materially in estimating absorption and excretion gradients in relation to time and concentration for many important types of drugs. One wishes, of course, to obtain a concentration which within a reasonable time will produce the desired effect, but which will not produce undesired effects even if maintained for a relatively long period of time.

The concentration of a chemical in any particular living tissue at any given moment after administration is calculated from the product of dosage (mass of chemical per mass of living material) and the ratio of the rate of absorption into the tissue to the rate of its removal from it. There is a direct relation between concentration and intensity of effect.

MECHANISMS OF DRUG ACTION

While the dose-effect relationship with regard to drugs was anciently implied as a scientific problem for pharmacology, the question of the mechanism by which drugs act was not raised in a scientific manner until the nineteenth century. Greek, Roman and medieval physicians developed elaborate theories of drug action with reference to the balance of "humors." Crude and easily observable physical properties of drugs, together with easily recognizable effects, were "fitted" into the humoral theory as well as possible. Drugs were assessed from the standpoint of their cooling, heating, astringent, caustic, purgative or other properties and used generally in an effort to obtain an idealized balance of humors. A powerful reaction against the severe abuse of drug therapy during the eighteenth century resulted in the effort under C. F. S. Hahnemann (1755-1843) to develop "homeopathy," in which ridiculously small doses of drugs were recommended. This attempt did, however, remind physicians effectively of the healing power of nature and indirectly assisted in a more systematic study of the mechanism of drug action.

With the development of modern chemistry, following the pioneering quantitative studies of A. L. Lavoisier (1743-1794), and the isolation and identification of the active principles of crude drug in crystalline pure form, it was possible for the first time to begin a quantitative study of drug action, with particular reference to mechanism. Francois Magendie (1783-1855) first undertook the study of the localization of the site of action of drugs. In this he was assisted by his remarkable English pupil James Blake (1815-1893). A study developed of factors determining the concentration of drugs in particular tissues, as a result of a survey of factors concerned in absorption and in destruction or excretion. Oswald Schmiedeberg (1838-1921) inaugurated systematic studies on the fate of drugs in the body when he found that chloral is reduced to trichloroethanol and conjugated with glycuronic acid to be excreted in the urine. The action of drugs was studied with reference to the point of application, not only with regard to precipitation of protein, but also with respect to possible reflex nerve responses. Studies were later made on the effects of drugs in transport through the body. This led to the first satisfactory scientific explanation of drug action, in the work of Claude Bernard (1813-1878) on the action of carbon monoxide in displacing oxygen from hemoglobin and thus producing all the effects of oxygen want.[13]

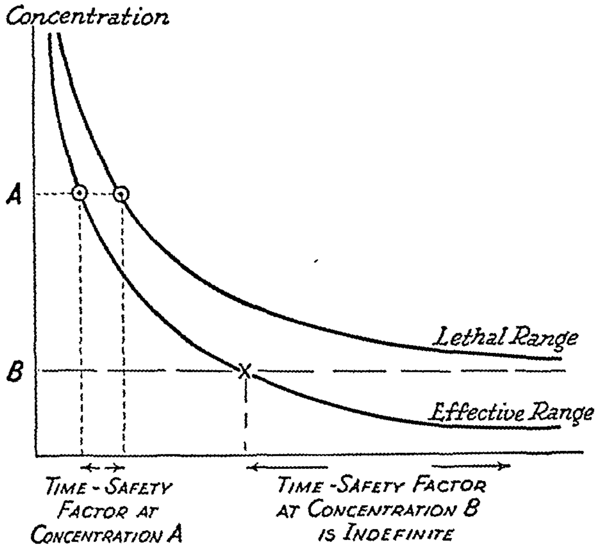

Fig. 3.—Time-concentration relations (example: inhalation anesthetics).

Following Blake's demonstration of chemical relationships in drug action, with reference to inorganic salts, A. C. Brown (1838-1922) and T. R. Fraser (1841-1919), in showing the curare-like effect of quaternary ammonium derivatives of various alkaloids,[14] emphasized an extreme physicochemical position in the mechanism of drug action. They postulated that the action of a drug is entirely a function of the chemical structure and energy relations of its molecule. This approach has been brilliantly developed with the introduction of many new useful drugs by a host of chemists, such as the German researchers stimulated by Willstatter, Ehrlich, Emil Fischer and Wieland, the French group influenced by Fourneau and Levaditi, the Swiss workers as Karrer, Meier, Ruzicka and Stoll, the English investigators as Cook and Robinson and such Americans as Adams, Alles, Fieser, Jacobs, Kamm, Major, Shonle, Small and SubbaRow. Unfortunately, physicians have little contact with such important scientific leaders in the development of drugs. It might help to ask them to discuss their work at medical meetings.

[14] Brown, A. C., and Fraser, T. R.: On the Connection Between Chemical Constitution and Physiological Action, Tr. Roy. Soc. Edinburgh **25**: 151-203, 1868-1869.

The chemical approach to the mechanism of drug action was modified slightly in the well known study of H. H. Meyer (1853-1939) and C. E. Overton on lipid solubility of narcotics.[15] In the famous side chain theory[16] of Paul Ehrlich (1854-1915) there was greater appreciation of the significance in drug action of physiologic factors involving the living material. Many modifications of Ehrlich's views are current. They have been thoroughly surveyed by Clark.[1] Extensions of Ehrlich's theories by Pauling are particularly interesting in relation to antibody formation.[17]

The leading contributors to modern pharmacologic theory are the English. General impetus has come from Sir Henry Dale and A. V. Hill. Stabilization of drug standards and of criteria for quantitative study of drug action has resulted from the fundamental work of Trevan, Gaddum, Clark and Burn. The mechanisms of drug action are being investigated by Haddow, Hawking, Ing, McIlwain, Peters, Quastel, Rideal and Yorke.[18] The English symposiums and reviews on current pharmacology are the most satisfactory of any available and deserve extended study.

Recent studies on the mechanism of drug action have been directed toward the basic units concerned, which are molecules of drugs in relation to living cells. This has been well explored by A. J. Clark (1885-1941) and his English followers.[1] Clark called particular attention to the relatively small size of the molecules of a drug in comparison to the relatively large size of the cells on which they act. He pointed out that the large number of molecules of a drug, even in a small mass, would compensate for the difference in size. However, in many instances, as with cholinergic or adrenergic compounds, the number of molecules capable of producing an effect can be explained only on the basis of chemical reaction with a small active patch on the surface of the cell.

Drug action is at a molecular level and involves relations between molecules of drug and molecules of cell receptors. Thus, investigation of the molecular architecture of cells, including the organization of the various cell interfaces, becomes prerequisite to further clarification of the mechanism of drug action. Such study reveals the significance of short range (van der Waals) association forces in drug-receptor relationships. The chief chemical factors involved are hydrocarbon, polar and ionic groups, with spacing and stereochemical factors determining the resulting forces of association. These forces vary in geometric proportion to the distances between relevant groups, suggesting the sensitiveness of the association forces to the orientation of the molecules concerned. Slight changes in spacing, dipole charge or ionization may form or split an association complex, thus accounting for high specificity and rapid enzyme reversibility. Competition between related chemicals in regard to receptor complexes in cell interfaces or other molecularly organized cellular structures results in effects determined by mass law equilibriums. The approach to pharmacologic problems through a study of molecular architecture of cells and receptor complexes permits an attempt to apply quantum theory to pharmacologic mechanisms, which has already shown to be so promising in connection with various mutafacient agents.[19]

Most of the current theories regarding the mechanism of drug action involve surface phenomena. These concern surface tension, polarity, template effects, blocking effects, "active patches" and a competitive effect involving essential metabolites in complicated enzyme systems.

In order to understand current theories of the mechanism of drug action, it is essential to know something about the surface organization of cells. According to the admirable summary by Davson and Danielli,[20] the cell surface is composed of a double layer of oriented lipid molecules, with single flattened molecules of protein spread on the outside and inside. These protein molecules may have reactive chemical groupings exposed to the surface, to which various compounds in the intercellular fluid, including drugs, may attach. On the other hand, certain ions may pass between the protein molecules and get into the lipid layer and eventually into the inside of the cell. Other compounds in the intercellular fluid may disrupt the proteins on the surface, dissolve the fats in the lipid layer and thus profoundly alter the surface tension with resulting injury or rupture of the cell. Certain molecules attaching to the surface of the cell may block other essential molecules from reacting with the cell in ordinary metabolism, thus altering the activity of the cell. It is now known that many chemicals, such as the sulfonamide drugs, act by interfering with essential metabolites, particularly vitamins, through competition involving similarity of chemical structure.[21] It is also now well established that many drugs, such as organometallic chemotherapeutic agents, act by disturbance of enzyme systems either on the surface of cells or inside cells.

An important point for physicians always to remember with respect to drug action is that drugs can only make cells do more or less what they are already capable of doing. No drug, for example, can make a muscle cell secrete urine. No drug can restore the functional activity of a cell so damaged as to be incapable of that function.

BIOCHEMORPHOLOGY: THE RELATION BETWEEN CHEMICAL CONSTITUTION AND BIOLOGIC ACTION

It is becoming increasingly important in a practical way for physicians to understand something about the relationship between chemical constitution and biologic action of drugs. This fascinating subject was first investigated by that remarkable gold rush physician, James Blake (1815-1893), who came to the United States after a short brilliant scientific career in London. About a hundred years ago he settled in St. Louis, joining later the gold rush to California. After a remarkable clinical and scientific career in California, which included meteorology, archeology, geology and zoology, he returned to his earlier scientific investigations on the relationship between chemical constitution and biologic action, with particular reference to inorganic salts. Anticipating Meyer and Mendeljeff by many years, Blake classified the elements into groups on the basis of the biologic action of their salts.[22] These groups, of course, correspond to what we now call the "periodic table."

It is interesting to learn what similarity of depressant action exists between the various members of the aliphatic organic compounds. Similarly, a common pharmacologic property of most alkaloids is rapidity of absorption and distribution and rapidity of destruction or excretion. On the other hand, all steroids, including vitamin D, sex hormones, digitalis and carcinogenic agents, are slow in action, with slow absorption and destruction, but the action lasts for a long time even from small dosage.

As we learn more about energy distribution and potentiality, we will be able more satisfactorily to predict possible biologic action of new chemical compounds. Indeed, some advance in this respect has already been made.

CLASSIFICATION OF DRUGS

The most satisfactory classification of drugs for the practical work of the physician is on the basis of the chief use of the drug. There are four major divisions into which drugs may be grouped on this basis: first, those drugs used chiefly for diagnosis, such as the halogenated phenolphthaleins; second, those drugs used chiefly for the prevention of disease, such as the vitamins and the antiseptics; third, those drugs used chiefly for "cure," such as quinine in malaria, and fourth, those drugs used chiefly for the alleviation of the symptoms of disease.

By far the greatest number of drugs used in medicine are employed for the alleviation of the symptoms of disease. These may be subdivided into the systems of the body on which the chief effect may be expected. Thus, one could treat of the drugs which act chiefly on the central nervous system, either as depressants or stimulants, those which affect the autonomic nervous system and its various divisions in either a stimulating or depressing way, those which act mainly on the heart and circulation, those which are used especially for effects on respiration, those which are employed usually in connection with the gastroenteric tract, those which generally produce effects on the excretory system, those which alter the endocrine system and those given chiefly for local effects on the skin.

It is important to remember that chemicals used for diagnostic purposes may have significant toxicity and thus deserve full consideration as drugs. Similarly, it is wise to recall that some of the vitamins used for the prevention of disease may under certain conditions have undesired effects and should also be considered from the standpoint of their general pharmacology. Drugs that are used for curative purposes are chiefly involved in the general field called "chemotherapy."

COMMENT

In a survey of this character, it is impossible to do more than suggest the many and various new types of chemicals which are finding significant practical application as a result of pharmacologic investigation. To discuss merely the new antihistaminic drugs, for example, would take many pages. Physicians will be wise to wait until reports are made on new drugs by the Council on Pharmacy and Chemistry of the American Medical Association. These reports are published, as appropriate, in The Journal. The wide variety and practical importance of these reports are indicated in the accompanying table, which lists those published in the first third of this year.

SUMMARY

When new drugs are acceptable for general clinical use, they are ordinarily described in detail in "New and Nonofficial Remedies." Physicians are cautioned to be sceptical of the descriptions of new drugs offered by pharmaceutic manufacturers in overly elegant brochures or other publications. It is safer and cheaper for the patient for physicians to restrict themselves to such drugs as are described in the "Pharmacopoeia of the United States," "The National Formulary" and "New and Nonofficial Remedies."

A matter of prime importance in the use of drugs, as in any technical procedure in medicine, is to weigh the hazards of the drug against the hazards of the disease. Only in a critical or most urgent condition is the physician justified in taking a risk for his patient through the use of a drug which may have untoward or dangerous effects. The physician should, of course, know thoroughly in advance what symptoms may appear as a result of toxic action and be prepared to counteract them promptly.

---

[22] Blake, J.: On the Influence of Isomorphism in Determining the Reactions That Take Place Between Inorganic Compounds and the Elements of Living Things, Am. J. M. Sc. 55: 63-76, 1848.

This discussion reviews in general terms some of the basic pharmacologic principles which may be useful in clinical practice. It emphasizes the value of acquaintance with such important concepts as drug standardization, factors determining the intensity of drug action, dose-effect and time-concentration relations and mechanisms of drug action. Suggestions are made as to what information about drugs is practically helpful for physicians to know. It rather hesitatingly indicates how much more efficient and economical physicians might be in the use of drugs if they would put more time to the study of fundamental principles in pharmacology and to the reports of the Council of Pharmacy and Chemistry of the American Medical Association and if they would restrict the drugs they use to those admitted to "New and Nonofficial Remedies" and the "Pharmacopoeia of the United States."

DERMATITIS RESULTING FROM CONTACT WITH MOTHS (GENUS HYLESIA)

Report of Cases

WILLIAM R. HILL, M.D.
A. DANIEL RUBENSTEIN, M.D.
and
JOSEPH KOVACS Jr., M.D.
Boston

Dermatitis as a result of contact with the brown tail moth (Euproctis chrysorrhea Linn) was first observed in the United States by White[1] in 1901. The rash was noted a few minutes to several hours after exposure to the cocoon, caterpillar or adult moth and either remained localized at the site of contact or became generalized. The most frequently occurring lesion[2] was a discrete erythematous maculopapule occurring singly or in groups, which in the cases of severe disease coalesced to form urticarial wheals. Steele and Sawyer[3] described wheals with vesicular or shallow necrotic centers. Pruritus was a constant complaint and was described as mild to intense; constitutional symptoms were not noted. The duration of the eruption varied from five to seven days, although in rare instances several weeks elapsed before resolution.

While it was recognized early that the dermatitis was provoked by the nettling hairs functioning as foreign bodies, it remained for Tyzzer[4] to demonstrate that a chemical substance present within the hair was capable of acting as a cutaneous sensitizer. This latter property could be destroyed by heat or alkali without altering the hair structure.

Dermatitis resulting from contact with other species of moths (genus Hylesia) has been reported in South America by Léger and Mouzels,[5] but so far as can be determined an eruption due to this genus has not been observed in the United States, where the genus does not occur.

It is the purpose of this paper to call attention to an eruption observed in 31 persons, members of the crew of an oil tanker, the *Wolfcreek,* who had been exposed to moths (genus Hylesia) in Cari Pito, Venezuela, and later on board the vessel during and immediately following its return voyage to Boston.

All but 2 of these patients were examined at the United States Marine Hospital, Brighton, Mass., on Feb. 23, 1947, at which time 4 patients, whose histories are reported in detail, were admitted to the hospital, remaining there for five days. Two types of cutaneous lesions were observed, one a localized form of grouped erythematous papules and papulovesicles, on the arms, legs or back, and the other a generalized urticarial variety suggesting morbilliform toxicoderma, most apparent on the flexor surface of the forearms, anterior aspect of the chest, abdomen and thighs (fig. 1, case 3).

For the most part the face, palms, soles and mucous membranes were devoid of lesions. In the majority of the patients the lesions appeared at intervals varying from a few minutes to several hours after initial contact, with an acute course and disappearance in four to seven days.

REPORT OF CASES

Case 1.—G. W., a 20 year old American merchant seaman, was admitted to the United States Marine Hospital, Brighton, Mass., on Feb. 23, 1947, with the complaint of a pruritic rash on the trunk, neck and extremities. He stated that on the night of February 15, a few hours after dropping anchor at Cari Pito, Venezuela, a swarm of moths invaded the ship. He and several other members of the crew killed a number of these by crushing them between their fingers, and later they exploded a dichlorodiphenyltrichloroethane (DDT) bomb in an attempt to destroy them. Shortly thereafter the patient noted several "small white itching bumps" on the uncovered skin of the abdomen at the belt line. The following morning the eruption had spread over the entire body with the exception of the face, palms and soles. He applied calamine lotion to the cutaneous lesions, which decreased the pruritus and resulted in a gradual subsidence of the dermatitis. The vessel remained in Venezuela for forty-eight hours to take on cargo, during which time he did not go ashore. On February 22 there was a recurrence of the generalized dermatitis.

Physical examination on February 23 revealed a well developed man whose only complaint was intense pruritus and who presented a diffuse urticarial eruption on the trunk, flexor surface of the forearms and lower part of the legs, anterior aspect of the thighs and neck. The individual lesions varied from 2 to 5 mm. in diameter, but here and there they had coalesced to form larger irregular wheals, some of which were palm sized. Many of the smaller lesions were surmounted by intact translucent vesicles or had excoriated surfaces. Pinhead-sized purpuric macules were scattered irregularly throughout the erythematous papules and were especially noticeable on the dorsal surface of the penis and on the lower part of the abdomen. The skin of the face, scalp, palms and soles was normal; the mucous membranes were unaffected. The remainder of the physical examination revealed no abnormalities.

During the hospital stay the temperature remained normal, and the rash subsided gradually without treatment. On discharge five days after admission the skin was entirely free of eruption.

The white cell count on admission was 6,350, with 67 per cent neutrophils, 22 per cent lymphocytes, 4 per cent monocytes and 7 per cent eosinophils. The hemoglobin (Westgren) was 14 Gm. The results of the urinalysis were normal, and serologic tests for syphilis elicited negative reactions.

Case 2.—W. S., a 26 year old American merchant seaman, was examined on Feb. 23, 1947, at the United States Marine Hospital, Brighton, because of dermatitis of the trunk, extremi-

ties, neck and ears. He, together with the patient in case 1, had swatted moths which entered the vessel on the night of February 15 and was present when a DDT bomb was exploded. Shortly thereafter he noted "itchy bumps" on the volar aspect of his wrists. By the following day the pruritus had subsided, but two days later the eruption had spread to involve the remainder of the skin, with the exception of the face, palms and soles. The patient stated that he had not been ashore in Venezuela and that the only native food he had eaten was bananas. He recalled an eruption which had occurred a few hours after handling DDT some months prior to the present eruption.

On admission the patient was observed to have an eruption similar to that described in case 1. The white cell count was 6,600, with 45 per cent neutrophils, 38 per cent lymphocytes, 6 per cent monocytes and 11 per cent eosinophils. The hemoglobin (Westgren) was 14.4 Gm. The urine contained 2 to 3 red cells per high power field, but this could probably be explained by the fact that the patient had a renal condition in 1945 requiring surgical intervention. The serologic reaction for syphilis was negative. During the hospital stay, a patch test was performed with a piece of sheet which had been used on the patient's bed on board ship, and no reaction was noted at the site forty-eight hours later. The eruption faded without treatment in two days, and he was symptom free on discharge at the end of five days.

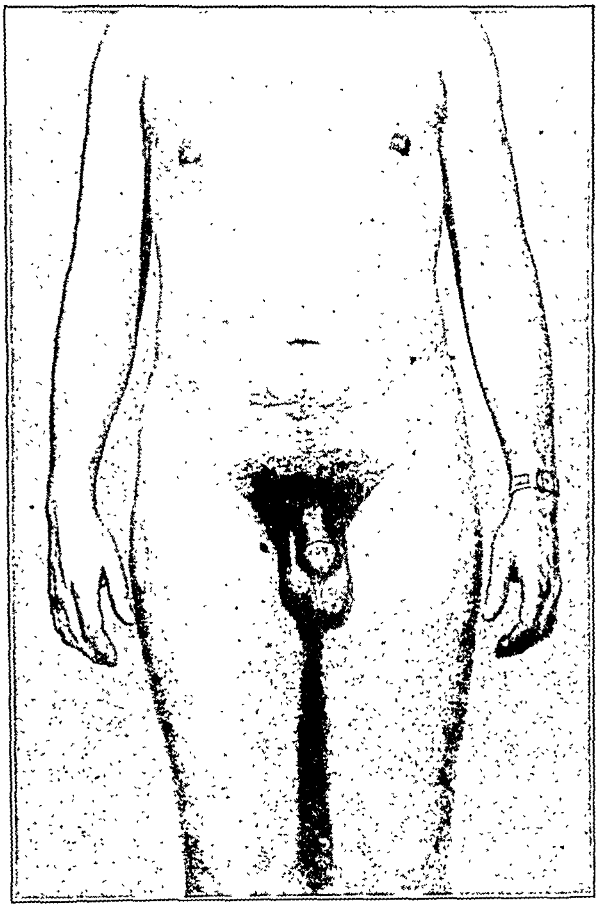

Fig. 1 (case 3).—Dermatitis due to moths of the genus Hylesia. Erythematopapular eruption on the trunk and extremities with scattered vesicles on the forearms. The large lesion on the anterior aspect of the right thigh is at the site of a patch test with hairs of the moth, which produced a positive reaction.

Case 3.—J. K., a 22 year old merchant seaman, had noted insect bites on his right upper lid on Feb. 16, 1947, the day of departure from Venezuela. However, it was not until arising on the morning of February 22 that he first noted the presence of itchy "small white bumps" on his chest and the flexor surface of his wrists. Twenty-four hours later the rash had spread to involve most of the body. With the exception of intense pruritus, there were no constitutional symptoms.

Examination on admission to the hospital revealed a diffuse erythematopapular hemorrhagic eruption of the trunk and extremities, together with edema of the eyelids. On the anterior surface of the forearms a few scattered vesicles were also seen (fig. 1).

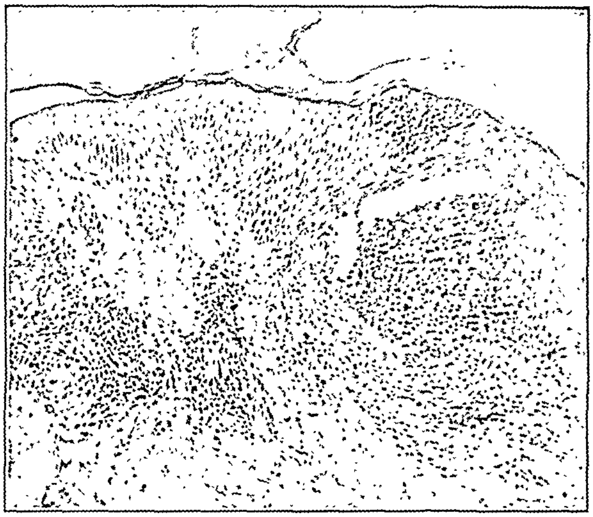

Fig. 2.—Dermatitis due to moths of the genus Hylesia. Photomicrograph (× 100) showing an intraepidermal vesicle and the acute nonspecific infiltrate in the upper part of the cutis.

The white cell count on admission was 5,250, with 57 per cent neutrophils, 32 per cent lymphocytes, 8 per cent monocytes and 3 per cent eosinophils. Urinalysis showed 2 to 4 white cells per high power field. Serologic tests for syphilis elicited negative reactions. Patch tests were performed with a piece of a new unused sheet, with a piece of sheet discolored by the moth and with hairs of the moth. The reaction to the test with the clean sheet was negative, but itching was noticeable within one-half hour of application and a violent papulovesicular eruption appeared at the test site twenty-four hours after the discolored sheet and the hair of the moth had been applied.*

Specimens for biopsy were removed from an urticarial papule on the forearm and from the skin at the site of the patch test with the moth hairs (fig. 2). The former of these sections of skin revealed diffuse vascular dilatation throughout the upper part of the cutis, together with a moderate perivascular infiltrate consisting of polymorphonuclear leukocytes. The collagen fibers in the upper part of the cutis were edematous and paler staining than those in the deeper layers. The epidermis was thickened, because of ballooning of the prickle cells. Polymorphonuclear leukocytes had invaded the epidermis from below and were seen in scattered foci in the intracellular spaces.

In the section of skin removed from the site of the patch test, forty-eight hours after the moth hairs were applied, a similar microscopic picture was observed, although in general the pathologic reaction was much more intense (fig. 2). The cellular infiltrate in the papillary layer of the cutis was denser and also more toxic, as evidenced by fragmentation of polymorphonuclear leukocytes. A profuse migration of these cells, small lymphocytes and eosinophils had taken place in the epidermis and had resulted in the formation of distinct intraepidermal vesicles. Spicules of moth hair were not observed, nor was a foreign body reaction noted in the cutis.

Case 4.—H. T., a 35 year old merchant seaman, was well until the day before admission, Feb. 22, 1947, when he first noted "bumps" on the back, which spread within a few hours to the arms, legs and abdomen. Except for pruritus, there were no complaints. On examination, the patient presented lesions similar to those of the aforementioned patients, except that those on the back had coalesced to form plaques 1 to 2 cm. in diameter. The white cell count on admission was 6,000, with 59 per cent neutrophils, 34 per cent lymphocytes, 4 per cent monocytes and 3 per cent eosinophils. Results of the urinalysis were normal, and serologic tests for syphilis elicited negative reactions. Ten minims of a 1:1,000 solution of epinephrine hydrochloride was administered subcutaneously every four hours for one day, without improvement. On discharge, five days after admission, however, the lesions had entirely disappeared.

EPIDEMIOLOGY

The distribution of cases according to the date of onset is shown in figure 3. Twenty-nine of the 31 persons included in the survey were examined at the United States Marine Hospital in Brighton; the others, both members of the original crew, were examined during an inspection tour of the vessel by one of us (A.D.R.). Not included are several cases in which the eruption developed in new crew members who boarded the ship while in Boston and recurrences which were noted among several of the original patients after they had returned to the ship.

The occurrence of 9 cases of dermatitis on Feb. 22, 1947, acquired epidemiologic significance when it was learned that all these patients had noted the eruption on arising in the morning, the bed linen having been changed on the evening before. Large brown stains were found on the sheets of several patients. The eruption had also been first noted in the morning among those in whom the cutaneous rash had developed on February 20 and 21. In these cases, also, the bed linen had been changed the evening before.

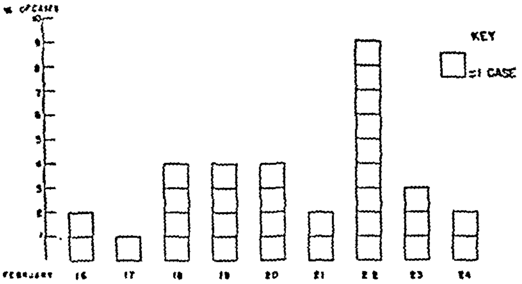

Fig. 3.—Dermatitis due to moths of the genus Hylesia. Chart of cases by day of onset.

Inspection of the closet where fresh sheets and other linens were stored showed a direct connection with the exterior by means of a wide-meshed metal barrier, sufficient to permit the entrance of moths. The bodies of several moths were found on the closet floor, and others had been suffocated between the stacked sheets.

Patch tests were performed on 1 patient (case 3) and on 2 volunteers who had not previously been exposed to the moth, both with the stained sheets and with hairs from the moth. The type of reaction (fig. 1) when the test was performed using the hair of the moth was similar in each instance to the lesions seen in the majority of patients and pursued a similar clinical course.

CLASSIFICATION AND CHARACTERISTICS OF THE MOTH

Several dead moths found on the ship were referred to the Museum of Comparative Zoology, Harvard University, Cambridge, Mass., for identification.

Mr. V. Nabokov, lepidopterist, identified the moths as females of the genus Hylesia; the species is nearest to Hylesia tapabex Dyar, but, owing to the defective condition of the specimens, the specific identification could not be established with certainty. These moths belong to the family Saturniidae, sometimes called, in English, peacock or silk moths. It consists of numerous species, around one hundred and ten having been described, but the group is so difficult to differentiate and so little known that probably some of the forms described as species are only races of one species. All of these moths are small and gray, with weakly falcated forewings and long coarse hair on the abdomen.

The species of Hylesia inhabit tropical regions of America. Several of them are known to cause dermatitis by the hairs which cover the abdomen. They are found on tree trunks, walls or fences in the daytime. Most of the known larvae are gregarious and undertake processional journeys in search of food. The female moths usually appear in large numbers at certain seasons and then migrate in swarms. They come freely to light, and this may explain their occurrence on shipboard, the vessels being provided with powerful lights.

COMMENT

The majority of patients, whose eruption developed during the return voyage to Boston and while in the port, stated that the initial lesions appeared on the flexor surface of the forearms, anterior aspect of the chest or thighs; in a few the neck or upper part of the back was the initial site. The incubation period ranged from a few minutes (cases 1 and 2) after exposure to several hours, as judged by the statement of patients who had retired in the evening in good health and who had noted an eruption on arising.

The initial lesion appeared to be an erythematous maculopapule or wheal, which in the cases of severe eruption became purpuric or vesicular. In a few instances the rash remained localized to the initial contact site, but in the majority a generalized eruption appeared within twenty-four to forty-eight hours, usually sparing the face, palms, soles and mucous membranes. Whether the generalized eruption indicated individual sensitivity, prolonged exposure to hair of the moth or a large amount of the inoculum could not be determined. Positive reactions to patch tests observed in 1 patient (case 3) and 2 volunteers who had not previously been exposed to the moths suggest that the hair of the moth acts as a primary irritant to which most persons are susceptible.

In all patients, the dermatitis was of short duration and lasted for four to seven days. Unfortunately, further follow-up was curtailed by the early departure of the vessel. It is interesting that the ship was held in quarantine because of the possibility that members of the crew were infected with a contagious disease. The history of contact with moths and the peculiar distribution of cases as to the time of onset were of considerable value in establishing the diagnosis and in removal of the quarantine.

Dermatitis observed in 31 persons in this series was produced by contact with the urticating abdominal hairs of female moths of the genus Hylesia, as shown by positive reactions to patch tests with the hair. The eruption may follow contact with living or dead moths, and the hairs may retain their irritating property over long periods of time, as evidenced by the appearance of the dermatitis eight or more days after the initial invasion. Indirect contact may occur when the urticating hairs are caught in articles of clothing, towels or sheets. Moth dermatitis should therefore be considered in the differential diagnoses of urticarial eruptions, especially in members of crews of ships or airplanes when ports of call include South American countries.

Removal of the patient from the source of contact, a soap and water bath, a change to clean clothing and application of an alkaline wash resulted in symptomatic relief within twenty-four hours. Diphenhydramine hydrochloride ("benadryl hydrochloride") and tripelennamine hydrochloride ("pyribenzamine hydrochloride") were administered to 16 patients orally in a dosage of 150 mg. daily for several days, without influencing the pruritus or the course of the eruption. Symptomatic relief was not obtained when 10 minims of a 1 : 1,000 dilution of epinephrine hydrochloride was administered subcutaneously every four hours for one day. Desensitization with extract material of the moth, as advocated by Steele and Sawyer,[3] who employed this method in a case of dermatitis due to contact with the brown tail moth, was not carried out in this series of cases.

SUMMARY

An outbreak of dermatitis resulting from contact with moths (genus Hylesia) is described.

Of 45 members of the crew, an eruption developed in 31 as the result of direct contact with urticating hairs of the adult moth.

The eruption occurred not only as a result of exposure to moths, but after contact with moth-stained bed sheets.

The diagnosis was confirmed by positive reactions to patch tests with moth hairs.

520 Commonwealth Avenue.

CYSTS (PERINEURIAL) OF THE SACRAL ROOTS

Another Cause (Removable) of Sciatic Pain

I. M. TARLOV, M.D.
New York

This communication calls attention to a pathologic entity that I described in 1938[1] as a chance encounter at autopsy. Cysts of the posterior sacral nerve roots seem to constitute another cause of the sciatic syndrome, which may be dealt with satisfactorily at operation.

Among the manifold causes of sciatica, herniations of the intervertebral disks have emerged as an important entity recently as a result of pathologic studies made by Schmorl and Junghanns,[2] followed by the important clinical work of Mixter and Barr.[3] A group of cases of backache or sciatica or both exist for which an adequate explanation has not been apparent. Moreover, explorations with negative results for protruded intervertebral disks have been carried out in approximately 10 per cent of the patients who presented rather characteristic symptoms and signs of this condition, requiring operation. Such an incorrect diagnosis was made in the present case, in which the clinical picture was observed to have resulted from the presence of an extradural cyst of the second sacral posterior nerve root and ganglion, the pathologic condition previously described[1] (figs. 1, 2, 3, 4 and 5). Removal of the cyst at operation resulted in complete relief from incapacitating symptoms and prompt recession of clinical signs. Exposure of the cyst necessitated removal of the cephalad part of the posterior arch of the sacrum, a procedure not ordinarily carried out in the course of operations for herniated intervertebral disks. Failure to do this may account for some of the negative disclosures in the surgical treatment of sciatica.

In 1938 in the course of dissections of the filum terminale in approximately 30 adults, while at the Montreal Neurological Institute, I encountered 5 cases of perineurial cysts on the extradural portions of the posterior sacral or coccygeal nerve roots.[4] The clinical significance of this experience was not appreciated at that time, although I believed that the cysts might, in the course of time, prove to play a part in the causation of certain cases of sciatica. In view of the present clinical case, this suspicion appears to have been confirmed. It therefore seems imperative to keep this possibility in mind and to carry out the simple necessary steps to establish the presence of such cysts, or to exclude them, in those cases of sciatic pain requiring operation and in which herniation of the intervertebral disk, or any other satisfactory explanation for the clinical syndrome, is not found.

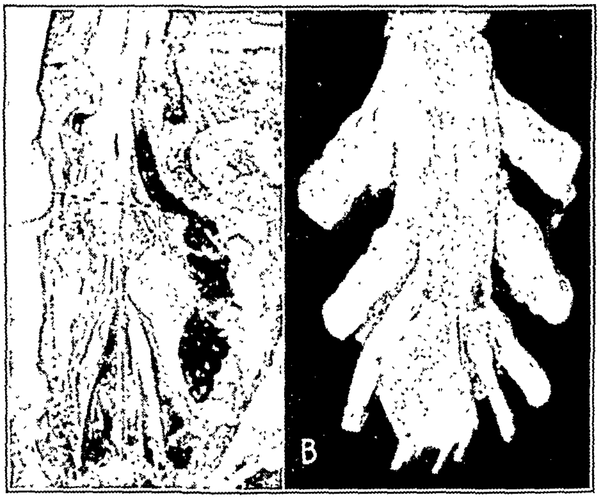

Fig. 1.—*A*, photograph taken at autopsy, showing a cyst (indicated by arrow) occurring on the second sacral nerve root. The cephalad margin of the posterior arch of the sacrum, which covered the cyst completely, is indicated by the broken line. *B*, photograph of a cyst arising from the third sacral nerve root and decidedly compressing the adjacent roots. The appearance of this cyst is essentially identical with that encountered at operation in the case reported. The specimens shown in this figure were obtained at autopsy at the Jewish Hospital of Brooklyn (by permission of Dr. David Grayzel, Department of Pathology).

REPORT OF A CASE

J. L., aged 42, was admitted to the Norwalk General Hospital, Aug. 29, 1947, because of severe pain in the region of her right hip and the posterior aspect of the right thigh, of eight months' duration, associated with a feeling of pressure, warmth and numbness extending from the hip posteriorly to the calf of the right leg during the latter month of her illness. The patient stated that she had been in good health, free from pain, until Christmas day 1946, when she tripped in her home striking her head, the lower part of the back and her hip against the

[4] Tarlov.[1] This high incidence of cysts encountered at autopsy in my series seems to have been confirmed recently in Sweden by Rexed,[5] who found arachnoidal proliferations and cysts in "8 cases out of 17 examined"—the "material consisted of the lumbar spinal cord with its nerve roots and first stretch of the spinal nerves enclosed in the dural sac." Rexed's statement, ". . . a search through the current literature revealed no description of this condition," overlooks my prior account (1938) of such cysts, which, however, were not associated with arachnoidal proliferations.

[5] Rexed, B.: Arachnoidal Proliferations with Cyst Formation in Human Spinal Nerve Roots at Their Entry into the Intervertebral Foramina, J. Neurosurg. **4:** 414-421, 1947.

andirons and hearth of the fireplace. She sustained a bump on her head and a bruise on her right hip and lumbosacral area. She went to bed because of pain in the regions of the bruise, but remained there for only two hours, and after two days she was able to resume her household duties without discomfort. Ten days after the fall slight pain developed in the right hip. This persisted until the first of February, when the pain became much severer. There was difficulty in getting out of a chair or engaging in any task which required her to bend forward or laterally. The severity of the pain gradually increased, and the patient experienced increasing difficulty in getting out of bed or in assuming any household activity. Early in June the pain began to radiate down the posterior aspect of the right thigh. The pain was relieved to some extent by heat and recumbency, but its severity gradually increased until the first of August, since which time she had been obliged to remain in bed. During the latter month of her illness, on getting out of bed, she experienced a disagreeable sensation of pressure, warmth and numbness extending from the right hip posteriorly to the calf of the leg.

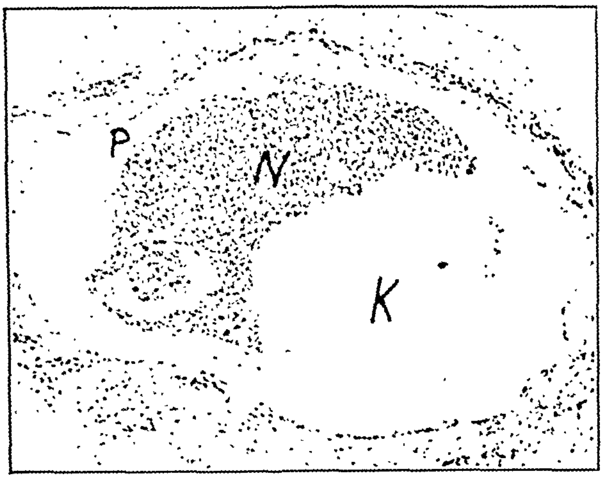

Fig. 2.—Microscopic appearance of a cyst discovered at autopsy and arising from the extradural portion of the posterior sacral nerve root. The cyst (K) may be seen occupying the perineurial space (P) and having excavated a portion of the posterior nerve root (N) (hematoxylin and eosin × about 76).

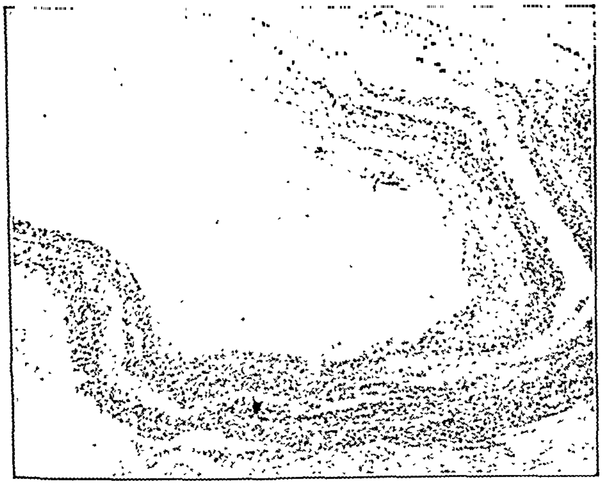

Fig. 3.—The cyst may be seen surrounded by nerve root substance (hematoxylin and eosin × about 41).

The patient was seen in consultation with her physician, Dr. Robert Patterson, on Aug. 8, 1947. The abnormal observations on examination at that time were: (1) well marked decrease of lumbar lordosis, (2) local pain on firm pressure over the fifth lumbar spinous process, (3) increase of pain along the posterior aspect of the right thigh on hyperextension of the back and also on right lateral flexion of the spine, (4) well marked decrease in power of dorsiflexion and, to a greater extent, of eversion of the right foot, (5) decrease in appreciation of pinprick of the outer aspect of the dorsum of the right foot and ankle and (6) absent right ankle jerk. It was my impression at this time that there was a protruded intervertebral disk, probably lumbosacral. Observations in roentgenograms of the lumbar and sacral aspects of the spine were normal. During the course of the next two weeks the patient suffered intense pain in the right lower limb and, in view of the severity of her discomfort, its duration and the fact that she was completely incapacitated, it was decided to carry out an interlaminar exploration for a herniated intervertebral disk. Myelography was considered unnecessary. It is of interest that when the patient was admitted to the hospital on August 29, for operation the next day, the observations were the same as aforementioned except that there was practically no pain on either hyperextension or lateral flexion of the spine. This fact tended to cast some doubt on the diagnosis of a herniated intervertebral disk, although operation was still clearly indicated.

Operative Procedure and Observations (August 30).—With the patient in the lateral recumbent position, right side uppermost, and under spinal anesthesia, later supplemented with intravenous injection of "pentothal sodium" (sodium 5 ethyl-5-[1-methylbutyl] thiobarbiturate), an incision was made just to the right of the middle exposing the spines of the fifth lumbar and first sacral segments. The soft tissue was separated from the spinous processes and laminas of these spines on the right side, and a hemilaminectomy retractor was introduced. The ligamentum flavum between the fifth lumbar and first sacral segments was removed, and the nerve root was clearly exposed. The root was in normal position and presented no abnormality whatever. The underlying intervertebral disk appeared normal. There was no bulge at all, but palpation of the lateral border of the disk revealed decreased resistance, and incision of the posterior longitudinal ligament and posterior part of the disk capsule enabled the forceps to enter the intervertebral disk for a distance of about 1 cm., with little force being applied to it. It was concluded that the disk presented a slight abnormality with respect to its decreased consistency, but could not possibly account for the clinical picture presented by the patient. There was not the slightest adherence between root and disk. The intervertebral disk and nerve root between the fourth and fifth lumbar segments were then explored, clearly exposed and observed to present no abnormality. The lower interspace was then reexamined, and it was observed that the epidural fat was being extruded from under the sacrum. As this fat was removed, a well marked bulge presented itself from

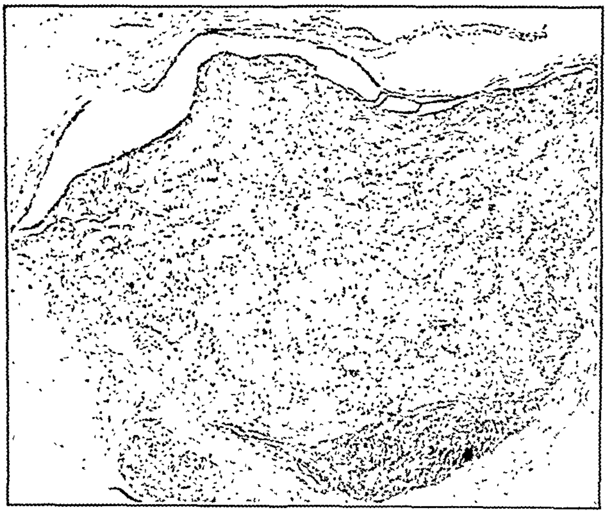

Fig. 4.—The cyst also occupied a portion of the perineurial space of the dorsal ganglion (hematoxylin and eosin × about 32).

under the posterior arch of the sacrum, just lateral to the margin of the thecal sac and medial to the nerve root (fig. 6). It was clear at this point that there was an abnormality under the posterior arch of the sacrum on the right side. Accordingly, removal of this portion of the arch was begun, and, as this was being accomplished, more and more of the lesion was brought into view. Finally, after removal of about 3 cm. of the posterior arch of the sacrum on the right side, full view of the cystic mass was effected. The lesion was present along the course of the second sacral root, which was enlarged in a fusiform manner. The tumor measured approximately 2 cm. in length and over 1 cm. in width, being about three times the width of the posterior root. It presented a reddish surface and was soft and fluctuant. Several large veins ran laterally along its course. The head of the table was elevated and then lowered, and no change in size of the cystic mass followed. Moreover, as the thecal sac was compressed, again no change in the size of the lesion occurred. Compression of the lesion itself did not obliterate its contents. It was then possible to conclude that the mass did not communicate with the subarachnoid space. A hypodermic needle attached to a syringe was introduced into the lesion, and an attempt was made to aspirate its contents. Only a few drops of fluid, pinkish as a result of admixture with blood and too little for analysis, was obtained, and the size of the mass did not diminish appreciably after the attempted aspiration. An incision was then made into the lesion and a portion of it excised. As this was done a decided decrease in the size of the remainder of the mass followed, as though escape of fluid contents through multiple small openings occurred. By means of a nerve hook it could be determined that the anterior nerve root was distinct from the fusiform mass which had clearly involved the dorsal root ganglion and approximately 1 cm. of the proximal portion of the nerve root. The entire lesion, including all but the distal end of the posterior ganglion at the point of its junction with the anterior root, was excised. There was no escape of cerebrospinal fluid during the procedure. The little bleeding that occurred was controlled by electrocautery and pieces of crushed muscle. The muscle was closed in two layers, the fascia in one layer, the subcutaneous tissue separately, and the cutaneous edges were also approximated with interrupted silk sutures. The patient's condition remained good throughout the procedure.

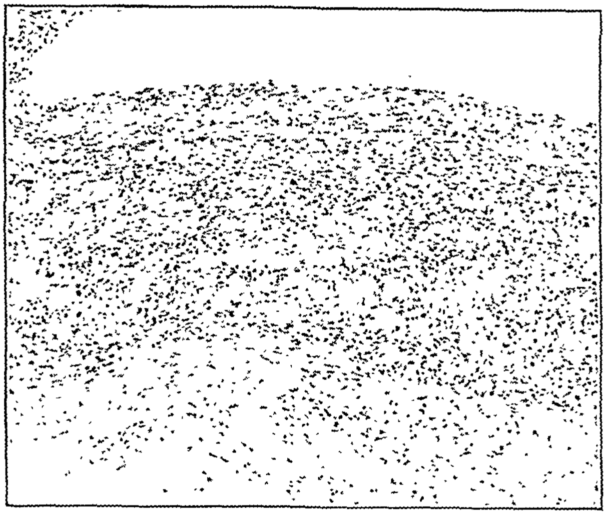

Fig. 5.—Nerve cells and other substance of the dorsal ganglion which formed a portion of the cyst wall (hematoxylin and eosin × about 80). (There is more detailed photographic depiction of the cysts shown in this figure and in figures 2, 3 and 4 in a previous description of this condition.[1])

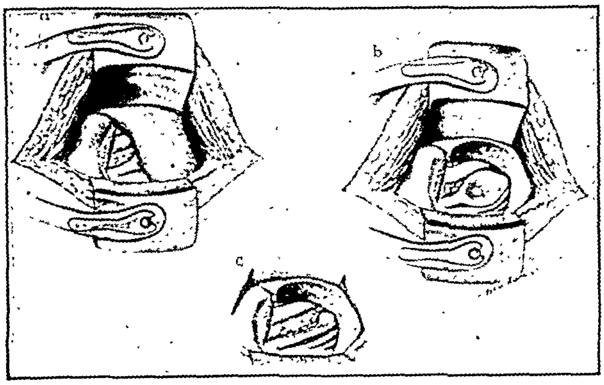

Fig. 6.—Sketches showing (*a* and *b*) appearance of cyst at operation and (*c*) the nerve root after removal of the cyst. In *a* the bulge of the cyst through the border of the sacrum was seen only after removal of the epidural fat in this region. Full view of the cyst arising from the posterior root of the second sacral nerve at its junction with the ganglion is seen in *b* after removal of a portion of the posterior arch of the sacrum. In *c* one sees the intact anterior root after removal of the cyst and corresponding segment of the posterior nerve root and dorsal ganglion.

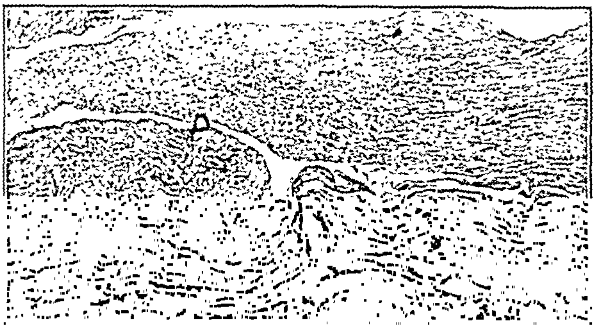

Fig. 7.—The cyst may be seen occupying the perineurial space (P) (hematoxylin and eosin × about 39).

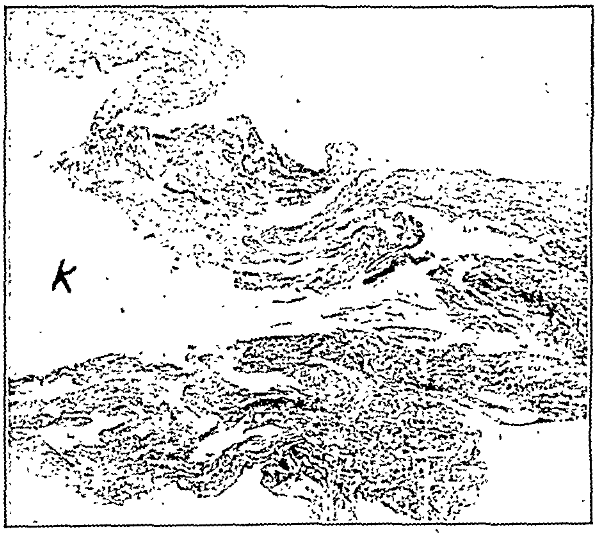

Fig. 8.—Photomicrograph of a portion of the cyst removed at operation, showing communication between the perineurial space and the main cavity of the cyst (K) (hematoxylin and eosin × about 28).

The patient made an uneventful convalescence from the operation. There was no difficulty in voiding or in the control of her bowels. The day after operation she was free from her previous lower limb pain, and there was a decided increase of power of the foot as well as in the appreciation of pinprick. Improvement continued, and on the seventh postoperative day, when the patient was allowed out of bed, power and sensation of the foot were entirely normal. The sutures were removed from the wound, which was well healed, at this time. The patient was discharged from the hospital on the eleventh postoperative day without any complaints and feeling happy with the result of the operation. She was last seen two months after operation, at which time she was carrying on with her full household duties. She complained of occasional mild darting pain of momentary duration in the posterior aspect of the right thigh, at the junction of the middle and lower thirds. At this site pinprick was associated with a somewhat diffuse "pins and needles" sensation. Otherwise examination revealed no abnormalities except for persistence of the absent right ankle jerk. The patient did not feel handicapped in any way.

The tissue removed at operation was fixed in 10 per cent formaldehyde and imbedded in paraffin. The following technics were then carried out on the sections: hematoxylin and eosin stain, Laidlaw's lithium silver carbonate impregnations for reticulin and collagen fibers; Gros-Bielschowski technic for axis cylinders, Spielmeyer's stain for myelin sheaths and cresyl violet preparations for ganglion cells.

Microscopic examination of serial sections of the various portions of the tissue removed at operation afforded the opportunity of reconstructing an accurate histologic picture of the lesion, which was a multiloculated cystic one (figs. 7, 8, 9, 10 and 11). The cyst occupied the posterior root abutting the proximal portion of the dorsal ganglion. Its main part was bordered by reticulin or by nerve fibers, some of which showed vacuolization, swelling and fragmentation of axis cylinders and myelin sheaths in Gros-Bielschowski and Weigert-Pal preparations, respectively. The degenerative changes affecting the nerve fibers were not widespread in the intact portions of the nerve root and occurred chiefly in certain regions of the wall of the cyst. Few of the ganglion cells adjacent to the cyst showed signs of chromatolysis consisting of pulverization and disappearance of Nissl's substance with migration of nuclei to a peripheral position, but most of the nerve cells appeared normal in cresyl violet stains. The cystic cavity communicated with the perineurial space and, in some regions, had caused considerable thinning of the overlying dural prolongation, the epineurium. Several miniature cysts were seen, occurring either as local dilatations within the perineurial space or as areas of fragmentation and rarefaction (figs. 9 and 11) within the parenchyma of the posterior root. There was no demonstrable communication between these various cysts. In a few areas bordering the cysts there were small accumulations of monocytes and lymphocytes, but this was not a prominent feature of the tissue and there was no evidence of recent or old hemorrhage or of neoplasm. No proliferative changes of the arachnoid or other tissues were present.

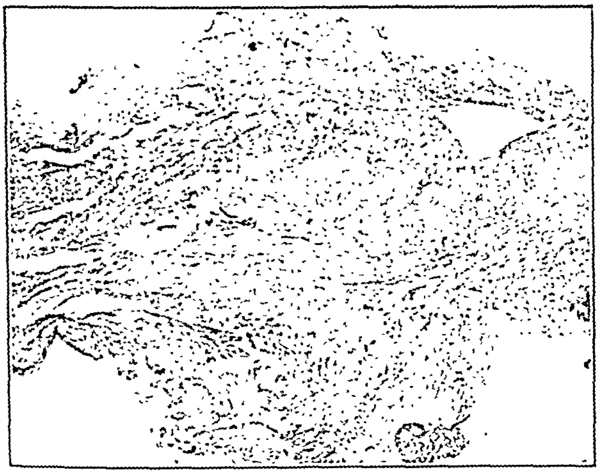

Fig. 9.—Smaller cystic spaces, resulting probably from rarefaction or a liquefactive type of degenerative change occurring in the posterior root, such as is also seen in figure 11 (hematoxylin and eosin × about 25).

COMMENT

There is no doubt that the patient's symptoms and signs were the result of the cyst which occurred along the extradural portion of the second sacral posterior nerve root, the lesion having compressed the neighboring roots. At operation a protruded intervertebral disk was not found. That the cyst was in position to have caused compression was shown by the fact that as the epidural fat just under the sacrum was removed a bulge of the cyst became apparent. More and more of this bulge appeared as the posterior sacral arch was removed bit by bit. The causal relationship between cyst and syndrome appears to have been confirmed by the postoperative course of the patient, whose sciatic pain, as well as motor and sensory abnormalities, almost entirely disappeared twenty-four hours after operation and were hardly demonstrable one week later. Although the presence of the cyst on the second sacral nerve root as well as the compression of the surrounding nerve roots may have accounted for the patient's severe pain, the motor and sensory signs must have been the result almost entirely of nerve root compression, since they vanished so quickly following operation. The fact that no sensory loss, but only a small area of paresthesia, could be observed following complete interruption of the second sacral posterior nerve root is in keeping with the conception of overlap of sensory dermatomes as demonstrated in animals by Sherrington and by Foerster[6] in human beings; this experience does not lend support to Keegan's[7] denial of such overlap.

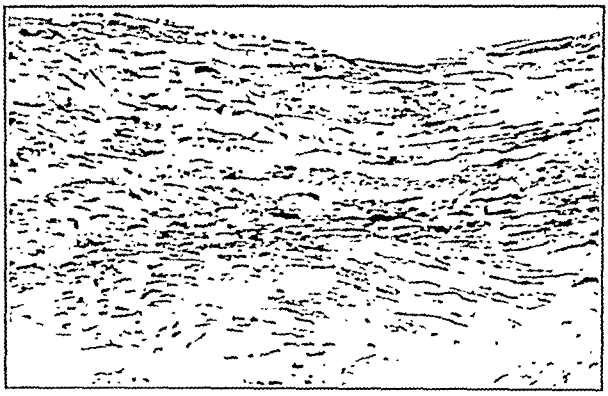

Fig. 10.—Axis cylinders occupying the wall of the cyst. Some of the axones have undergone swelling and fragmentation as a result probably of compression by the cyst (Gros-Bielschowski technic for axis cylinders × about 89).

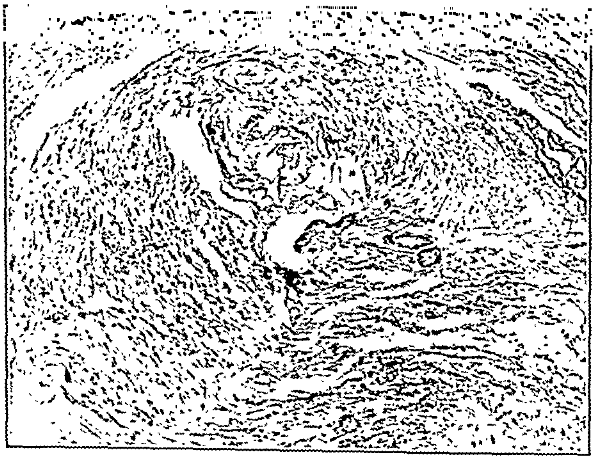

Fig. 11.—Photomicrograph showing degenerative change occurring in the posterior root (hematoxylin and eosin × about 73).

[6] Foerster, O.: The Dermatomes in Man, Brain **56:** 1-39, 1933.

[7] Keegan, J.: Dermatome Hypalgesia Associated with Herniation of Intervertebral Disc, Arch. Neurol. & Psychiat. **80:** 67-83 (July) 1943.

It is significant that the cyst was not seen while exploration of the lumbosacral interspace for herniated disk was being carried out, although the first sacral nerve root was clearly exposed. The presence of the cyst might have been overlooked if the epidural fat just cephalad to the sacrum and under the rim of its posterior arch had not been removed. Only after removal of the cephalad 2 cm. of the posterior sacral arch on the right side was the lesion exposed in its entirety. It is therefore important to unroof the sacrum in order to determine whether perineurial cysts, especially those arising from the lower sacral roots, are present, since in the course of the ordinary interlaminar exploration for herniated intervertebral disks the region from which such cysts arise is not brought into view. It is possible that such lesions may be responsible for the sciatic syndrome in an appreciable number of the cases in which results of interlaminar exploration for protruded intervertebral disks prove negative. The technic of unroofing the sacrum is, of course, simple in the hands of competent surgeons and does not result in any weakening effect on the spinal column.

In the case reported the syndrome of sciatic nerve root compression appeared clearcut, so that myelography was unnecessary. If a myelogram with ethyl iodophenylundecylate had been done, it is unlikely that there would have been any apparent defect, since the cyst occupied a position 1 cm. or more distal to the origin of the nerve root from the thecal sac and it was not in continuity with the subarachnoid space. Unless the cysts attain a very large size, so that compression of the thecal sac or deformation of the short segment of arachnoid prolongation over the nerve root occurs, myelography would be of no value in establishing the diagnosis. However, I have had some experience recently with extradural myelograms, carried out after the injection of ethyl idiophenylundecylate ("pantopaque") into the lumbosacral epidural space. In some of these cases it has been possible to outline the lumbar and sacral nerve roots. It is possible that further experience with this technic may make it possible to portray roentgenographically perineurial cysts and other intraspinal lesions which arise from outside the limits of the subarachnoid space and thus establish the diagnosis before operation.

That the contents of the cyst did not communicate with the subarachnoid space is shown by the following observations: First, elevation and lowering of the head of the operating table did not alter the size of the cyst or the tension within it; second, compression of the cyst did not obliterate its contents, and, third, during the process of incision of the cyst and complete removal of it piecemeal, escape of cerebrospinal fluid did not occur.

The trauma which the patient sustained approximately ten days before the onset of her pain is rather suggestive of a causal relationship to the cyst, although not necessarily so. Histologic examination of the cyst showed no evidence of recent or old hemorrhage, which, if present, might have favored a traumatic origin. The cyst proved to be of the same histologic structure as the cysts encountered at autopsy.[1] They were not neoplastic, parasitic or dermoid, and there was no striking evidence of an inflammatory origin. The areas of rarefaction within the nerve root indicate a possible degenerative genesis. This possibility is supported by chemical examination of the cyst contents in a case encountered at autopsy. The total protein content of the cyst fluid was that of normal cerebrospinal fluid, but the potassium content was 62.5 mg. per hundred cubic centimeters, over four times that of normal cerebrospinal fluid.[8] This observation suggests degenerative changes affecting cells, which contain large quantities of potassium.[9] It should be stated that microscopic examination of the cyst fluid revealed no cellular elements within it. Whether similar cysts occur at higher levels is uncertain, since the autopsies [1] did not include examination of the dorsal ganglions of the entire spinal axis. Such a study, however, is now under way.

The exact incidence of perineurial cyst as a cause of sciatic or other nerve root pain remains to be determined. However, in view of my experience in autopsies in which such cysts were seen in 5 out of a total of 30 cases in which the spinal cord was examined, the clinical encounter of perineurial cysts may prove to be far from rare, if sought for. It is possible that, as clinical experience with this lesion accumulates, certain symptomatologic features or physical observations may emerge as leads in the preoperative diagnosis of this condition.

CONCLUSIONS

1. Perineurial cysts arising from the posterior sacral nerve roots can produce the sciatic syndrome.

2. In patients suffering from the sciatic syndrome thought to be due to a herniated intervertebral disk, requiring operation and in whom interlaminar exploration fails to reveal a protruded disk or other abnormality sufficient to have accounted for the pain, removal of the posterior arch of the sacrum should be done in order to determine whether a perineurial cyst is present. Moreover, in patients with persistent severe sciatic pain following negative results of explorations for herniated intervertebral disks, and in whom the known causes of sciatica have been excluded, consideration should be given to the advisability of exploration for sacral perineurial cysts. By following this practice the incidence of negative results of explorations in the surgical treatment of sciatica will probably be reduced.

Second Era of Research in Chemotherapy.—During the past dozen years we have all witnessed the impact on medicine of what Sir Henry Dale has called the second era of research in chemotherapy, as manifested practically in the unparalleled usefulness of the sulfonamides, penicillin, and the newer antimicrobic drugs, and theoretically in the impetus which their discovery has given to new thought and experimentation on the metabolism of parasitic cells, the mechanisms of drugfastness, and the general principles of chemotherapy. Great as these achievements are, they were exceeded, in my opinion, by the attainments of bacteriology in the final quarter of the 19th century. For in that remarkable efflorescence, the genius of Pasteur, the logic of Koch, and the percipience of Lister permeated medicine with incredible rapidity, the immediate consequence being that a host of diseases which had puzzled and plagued mankind for centuries abruptly yielded their causes, and often their cures in addition, as fruits of the new science, while a vastly more important outcome was the fact that man had at long last identified and begun to study the bacterial creatures with which he lives.—Kidd, John G., *Bulletin of the Johns Hopkins Hospital,* June 1948.

GENERAL PRACTITIONERS SESSION

THE CHRONIC INVALID

EDWARD L. BORTZ, M.D.
President, American Medical Association
Cleveland

PREVALENCE

The patient with chronic illness is one of the major challenges to modern society. Sooner or later some form of long term illness affects one or more members in most families of the nation. A conservative estimate suggests that more than one sixth of the population—some 25,000,000 persons—are afflicted with some chronic disease.[1] Approximately 2,000,000 of our population are chronic invalids at the present time, and the number is steadily increasing. It will increase still more as the control of other disorders which were so devastating heretofore is now being more effectively managed. The mortality rates from acute infections, nutritional deficiencies, glandular abnormalities, are falling. Many patients afflicted with cancer are being cured because of earlier diagnosis and complete eradication.

A report from New York State estimates that 7 out of every 10 deaths are due to some chronic illness. And while in 1900 chronic disease was the cause of 26 per cent of all deaths in New York, in 1940 almost 70 per cent of the fatalities resulted from prolonged illness. No age is immune. Some 40 per cent of the patients suffering from chronic illness are under 45 years of age, and in patients between 25 and 64 years of age, 60 per cent of the reported cases of long term illness are found. Chronic illness is also found among children, adolescents and those in the young adult years.

The extent of this problem is expanding. Inadequate persons, such as persons with mongolism and other unfortunates, formerly were frequently removed by a severe infection or some nutritional discrepancy. Now the control of these maladies is carrying over larger numbers of persons who are charges on society. The strain on family budgets and household organization is mounting. It therefore becomes necessary for planning on a much broader scale to meet the challenge of chronic invalidism.

The need for comprehensive planning to meet the challenge of chronic disease must be emphasized. While the economic and social aspects are of vital importance, the highlights in the problem of the chronic invalid are prevention, management and research. Since each year approximately 1,000,000 deaths are due to chronic illness and a billion days are lost from productive activity, it is high time that concerted action on a broad plane be directed to counteract this huge loss to our social existence.

As more persons are living longer, there is more opportunity for chronic illness to develop. To this extent aging of the population may be regarded as a contributory factor. However, it should be kept in mind that aging and chronic invalidism are not synonymous by any means. The misconception that old age is constantly visited by chronic invalidism must be dispelled. Many persons now have a vigorous and enjoyable senectitude free of prolonged illness.

Long term illness is one of the principal causes of economic hardship. The presence of a chronically ill patient in the family frequently alters the psychologic atmosphere within the home. When an attitude of defeatism is adopted by the patient and those around him, the outlook is likely to be hopeless.

THE MAJOR CHRONIC ILLNESSES

The major chronic illnesses are as follows: cardiovascular disorders, including arteriosclerosis, apoplectic stroke, rheumatic heart disease and syphilitic heart disease; the arthritic and rheumatic disturbances; mental diseases; advanced cancer; tuberculosis; diabetes; gastrointestinal disturbances of organic or functional origin; disorders of the genitourinary tract; the allergic states, and chronic alcoholism. Some 4,000,000 invalids are suffering from chronic heart disease. Vital statistics indicate that approximately 600,000 lives are lost each year as a result of a breakdown of the cardiovascular system in the form of cerebral hemorrhage, coronary occlusion or chronic heart failure. It has been estimated that approximately 10 per cent of all chronic disease cases fall into the group of cardiovascular disorders.

Arthritic and rheumatic disorders stand second on the list of the most common disabling afflictions—the exact number of invalids suffering from arthritis is not known. Available statistics are not satisfactory. This is because of the variation in terms and lack of exactness in diagnosis. There is a great need today for statewide surveys which will give a clear picture of the magnitude of the problem of chronic disease. With arthritic and rheumatic disorders, for instance, it is important to know the number of patients suffering from degenerative joint lesions, those suffering from acute infectious arthritis and the number in which a metabolic abnormality, such as gout, is the underlying factor. To know the extent of the problem is the first essential in a program of combating the ravages.

According to a recent summary[2] there are 641,331 beds for general hospital cases with an average census of 496,527. There are 674,930 beds for cases of nervous and mental disease with an average census of 635,769. With the use of shock therapy for certain types of mental illness the number of admissions to hospitals is increasing, while, at the same time, the length of stay is being reduced.[3]

This year approximately 180,000 lives will be lost because of cancer. It may be conservatively estimated that 75 per cent of these patients are bedridden or otherwise incapacitated to such an extent as to be classified as chronic invalids.

With the superb work of various organizations interested in the control of tuberculosis, the death rate is decreasing in those areas where modern health measures have been instituted for its control. According to statistics from the National Office of Vital Statistics, in 1945 there were 52,916 deaths—a ratio of 40.1; in 1944 there were 54,731 deaths—a ratio of 41.3, while in 1943 there were 57,005 deaths—a ratio of 42.6. It is unfortunate that there is no uniform method for reporting cases of tuberculosis. While there are not any accurate data on the total number of persons suffering from tuberculosis, various authorities have

[2] Arestad, F. H., and Westmoreland, M. G.: Hospital Service in the United States, J. A. M. A. **133:** 1065 (April 12) 1947.

[3] Smith, L. H.: Personal communication to the author, Sept. 25, 1947.

estimated that at the present time there are approximately 1,500,000 patients. It should also be stated that tuberculosis is still the captain of the men of death in areas where modern control measures are not utilized.

While diabetes is listed as a chronic disease, and there are probably 2,000,000 persons with diabetes in the country at the present time, few of these are invalids. Modern control measures have greatly improved the status of the diabetic patient.

The high pressure of social existence at the present time is reflecting itself in the large number of persons suffering from some form of gastrointestinal disorder—the most frequent being peptic ulcer or colitis. Grouped with disorders of the gastrointestinal tract may be those conditions of chronic involvement of the biliary tract. Here, too, persons ofttimes are not sick and not well, but become chronic sufferers because of low grade efficiency.

With increasing years approximately 50 per cent of the male population becomes afflicted with prostatic hypertrophy. As the cardiovascular system becomes sclerotic prostatic lesions may be more pronounced.

It is estimated that 1.5 to 2 per cent of the population are chronic sufferers from some allergic condition, although they may not be incapacitated for long periods of time.

Chronic alcoholism must be regarded as a menace to the public health. Its devastations carry far beyond the destructive effects on the individual patient. A condition which has destroyed so many brilliant careers, disrupted so many homes and caused as much unhappiness as chronic alcoholism must be regarded as an important problem in the realm of chronic illness. The periodicity of bouts merely emphasizes the chronicity of the condition. While no accurate statistics are available, it has been estimated that there are 75,000 alcoholic addicts in the United States.[4] Although the alcoholic addict frequently is a social problem with the legal aspect, basically the condition is medical and needs concentrated study, the same as other chronic medical disorders. The National Committee for Education on Alcoholism and the organization known as Alcoholics Anonymous have rendered outstanding public service in emphasizing the need for rehabilitation of the problem drinker.

SOCIAL FACTORS

Long term illness produces an added burden on the patient's family. It adds one more problem case to the social agencies who exist for the purpose of neutralizing adverse social influences. If the invalid is the wage earner, the family's economic predicament becomes immediately acute, and economic dependency on society may result.

According to the National Health Survey,[5] chronic illness occurs most frequently in families with relatively limited financial resources. The rate of chronic illness found in families on relief in 1937 was about double that for families with incomes of $2,000 to $3,000 per year. The New York State Health Preparedness Commission in 1944 found in their investigation that some 37 per cent of persons receiving old age assistance were afflicted with some form of chronic illness, just double the average for their age group. As pointed out by Howard Rusk,[6] long term illness depletes earning power at a time when the patients are called on to pay more for their care than those who are suffering from an acute illness. An important additional burden is the common tendency on the part of the invalid to become a permanent dependent. Psychologic factors, such as boredom, lack of initiative to improve one's status and the acceptance on the part of relatives that the condition cannot be bettered, are some of the chief obstacles which must be removed if the chronic invalid is to be rehabilitated. Too many patients accept their illness with resignation and appear to be willing to become charges on society. A rehabilitation program has much to offer these persons.

DEFEATISM AND FEAR

Although chronic illness may occur in any age group, it is likely to be more devastating for older persons in society. Rusk[6] has emphasized the fear of chronic disease and disability as the most haunting spector of increasing age. In 1936 the National Health Survey indicated that 58 per cent of all persons 65 years and over suffer from some form of chronic illness or physical disability. It should be emphasized that there are many persons with some physical infirmity who are useful and productive members of society. It has frequently been pointed out that some form of chronic illness may teach persons the advisability of living a restricted existence, thereby enabling them to live out their normal life span. A psychologic atmosphere of defeatism and fear of the future is a major detrimental influence in perpetuating chronic illness. Greater attention to the patient's attitude and the creation of a buoyant and hopeful atmosphere are the first step in a sound rehabilitation program.

INSTITUTIONAL CARE

Persons with acute illness, particularly those due to the common infections, nutritional deficiencies and glandular disorders, are no longer in need of hospital care. A larger percentage of patients with chronic illnesses are now occupying hospital beds. Even so, because of the increase in the number as more persons grow into the later years, there is an acute shortage of beds for patients suffering from long term illness. It has been determined that 2 beds per thousand of the population are necessary for these patients. Few communities are equipped at the present time to care adequately for the number of patients who are chronic invalids.

It is generally agreed that the majority of these patients can best be cared for in the home or ambulatory clinic. Professional assistance from visiting nurse societies has been an invaluable aid in caring for chronically ill patients in their own homes. Here, too, demands are steadily increasing, and the estimated minimum of 1 nurse per two thousand of the population to participate in the nursing activities for chronic invalids is far short of the required optimum.[7] Since there is such a drastic shortage of professional nurses, wider use should be made of practical nurses and nurses' aides working under the supervison of the public health nurse. These aides should be able to perform the less specialized procedures under the supervision of a professionally trained nurse.

The hospital care for long term illnesses needs to be geared to their particular requirements. It has already been pointed out that the tendency to establish hospitals for chronic disease in areas remote from medical centers is unfortunate.[1] Stagnation is too likely to occur when patients are relegated to an institution where custodial care too often exists in the absence of an aggressive medical program for improving the patients' chances for rehabilitation. Therefore it is an established principle that, wherever possible, special departments in general hospitals should be created for the care of persons suffering from long term disease.

Where invalidism is likely to be permanent and progressive, nursing homes, either public or private, are the answer. Here again there is a dearth of facilities. In all of the metropolitan areas of the nation the need for more nursing homes is evident.

PREVENTION AND PROPHYLAXIS

Energetic and well organized programs for control have brought about a substantial reduction in the mortality rate of pneumonia, typhoid, smallpox, diphtheria and scarlet fever. Public education in reference to venereal disease should greatly limit the ravages of this prevalent nuisance. The early detection of cancerous growths, when these are localized and if they are completely eradicated, will substantially reduce the mortality rate from cancer. Here again, the need for cooperation on the part of all agencies interested in health is a basic essential. If health is the nation's greatest asset, a positive health program with regular health surveys should be set up as part of the school systems of the country. Industry and labor have an excellent opportunity to play a dominant role by establishing health surveys of all employees. The major industries and the school systems of the nation together, in collaboration with medical authorities, should create a program for positive health which, among other benefits, should be able to uncover incipient lesions at a time when their eradication is possible.

Hospitals should, in reality, become health and diagnostic centers where practicing physicians might refer their ambulatory patients for diagnostic surveys in all problem cases. In the past, the practice of limiting hospital services to bed patients was not in the spirit of early diagnosis and prophylactic services. The point of view needs be changed from that of curative to that of preventive and prophylactic medicine in the field of health. Health rather than sickness should be stressed.

In a health educational program, as persons learn their vulnerable points and tend to reinforce themselves against possible breakdown, chronic illness may less likely occur. In the last analysis, each person is responsible for his own well-being. He should make an appraisal of his physical assets and know his liabilities, and plan accordingly for the future.

TOMORROW'S HEALTH

Our health tomorrow depends on our researches of today. The next substantial increase in the life span will occur when the two great killers, vascular degeneration and cancer, are brought under control. These maladies destroy three quarters of a million citizens every year. Unless measures for control are developed, as folks grow into the vulnerable years, this number will increase. What can be done about it?

The great need is a clearer understanding of the progression of events occurring in the blood vessels and cells of the body, which appear as blood vessels deteriorate and as cells lose their objectivity and become cancerous. New tools of the greatest significance are now available for accurate examination of the steps by which normal tissues deteriorate and either break down or become cancerous. With the use of radioactive isotopes, which serve as neon lights, information of great practical value should be made available concerning the basic causes of vascular degeneration and cancer. As tagged atoms of carbon, calcium, iron, phosphorus, sulfur and the others are followed through the body, the intermediary metabolism of the various food stuffs should be clarified. Earliest deviations from the normal will be identified, and a better understanding of the pathologic physiology should ultimately lead to effective measures of control. Here, as I see it, is the great opportunity for modern science.

As the physical disorders—the major killers—are being subjected to critical study, the need for research in the field of psychiatric and psychosomatic afflictions is evident. The technics that lead to new insight into the processes of physical breakdown should give us more knowledge of our mental processes. We are facing a new day in the realm of medical science. Medicine has much to offer a world which is suffering from insecurity and which longs for peace of mind. A more vigorous and a more healthy population, steadily waging a successful battle for the control of the devastating diseases which afflict our fellow men, should be well equipped to study ways and means for bringing about a more stable social order.

Clinical Notes, Suggestions and New Instruments

PROLONGATION OF ACTION OF HEPARIN

JEFFERSON J. VORZIMER, M.D.
LEON N. SUSSMAN, M.D.
and
MAXWELL J. MARDER, M.D.
New York

An ideal anticoagulant should be easy to administer, have a prolonged action and be free of harmful side effects. It should be relatively inexpensive and should not require frequent laboratory control for its safe administration. Neither heparin nor "dicumarol," as now commonly used, satisfies these requirements. Heparin[1] has well known pharmacologic advantages over "dicumarol," but the necessity of repeated intravenous injection plus its high cost have acted as a deterrent to its common use. "Dicumarol"[2] necessitates daily venipuncture and repeated prothrombin determinations, and it is difficult to control its action because of the fluctuation in its effects. Search for a more ideal anticoagulant has resulted in various preparations of heparin, all of which attempt to facilitate its administration. Thus Loewe and his co-workers[3] used Pitkin's menstruum as a vehicle for subcutaneous use of heparin, and Stats and Neuhof[4] injected intramuscularly a concentrated aqueous solution of heparin.

During the past year we have been studying the effects of the administration of heparin in various menstruums calculated to prolong the anticoagulant action of the drug. After many

experiments in which the amount and concentration of heparin were varied, with different kinds and quantities of menstruums, we were able to obtain prolongation of the coagulation time[5] to from 200 to 900 per cent of normal for seventeen to twenty-four hours with a single intramuscular injection of heparin.

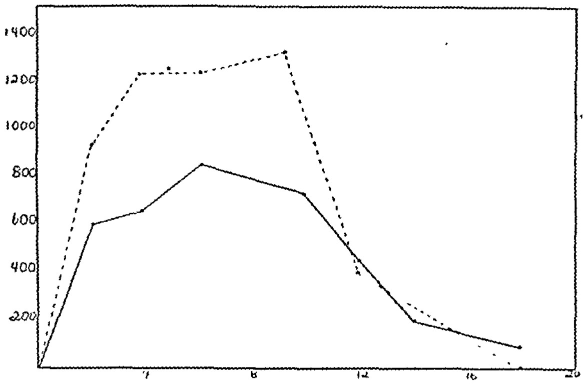

Fig. 1.—Graph of coagulation time (percentage of normal, vertical column of figures) in 2 cases (one represented by the broken line and the other by the unbroken line), showing the effect of administration of 200 mg. of heparin in 1 cc. of aqueous solution emulsified in 1 cc. of menstruum. The horizontal row of figures shows the number of hours after the injection.

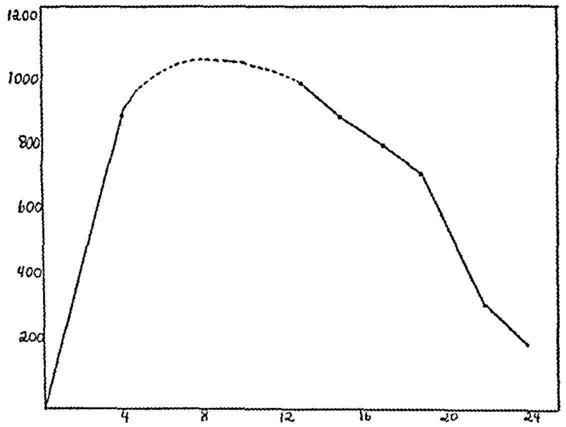

Fig. 2.—Effect of the administration of 300 mg. of heparin emulsified in 1 cc. of menstruum. The vertical column of figures shows the coagulation time in percentage of normal, and the horizontal row of figures indicates the number of hours after the injection.

Data for Eleven Subjects

Patient	Weight (Lb.)	Heparin Dose (Mg.)	Coagulation Time, Percentage Above Normal at Peak	Duration of Therapeutic Effect* (Hr.)
1	135	200	1000	16
2	107	200	900	17
3	126	200	1400	17
4	166	300	800	17
5	140	300	600	17
6	160	300	400	19
7	115	300	900	24
8	120	300	700	15
9	103	300	1100	20
10	134	300	500	18
11	115	300	1400	20

* Two hundred per cent of normal.

This simplification of heparin administration was effected by the use of concentrated heparin[6] (200 mg. per cubic centimeter of aqueous solution) emulsified in 1 cc. of a mixture of cholesterol derivatives (35 per cent), peanut oil (65 per cent) and beeswax (2 per cent). It was observed that approximately 1.5 to 2 mg. of heparin per pound of body weight was necessary to maintain this effect. If the volume of menstruum and the volume of heparin solution were kept equal, the sustained action of the heparin could be assured. There was no hemorrhage at the site of injection, and pain was negligible. Despite prolongation of the coagulation time to from 600 to 900 per cent of normal, in 1 case to 1,400 per cent of normal, no bleeding occurred. The injection had no toxic effects. Controls, illustrated in figure 4, demonstrated that the menstruum alone had no effect on coagulation time, whereas the injection of 1 cc. of aqueous solution of 200 mg. of heparin produced an increase in the coagulation time of only six hours' duration.

SUMMARY

The anticoagulant effect of heparin was prolonged by incorporation of this substance in various menstruums. A concentration of 200 to 300 mg. per cubic centimeter of aqueous heparin solution emulsified in an equal quantity of menstruum composed of cholesterol derivatives (35 per cent), peanut oil (65 per cent) and beeswax (2 per cent) gave the most satisfactory prolongation of the coagulation time. With this technic the coagulation time of the blood was prolonged from 200 to 900 per cent of normal for a period of seventeen to twenty-four hours after a single intramuscular injection. The dosage of heparin varied with the weight of the patient, approximately 1.25 to 2 mg. per pound of body weight being required. Further experiments involving the use of vasoconstrictors and other menstruums are being conducted.

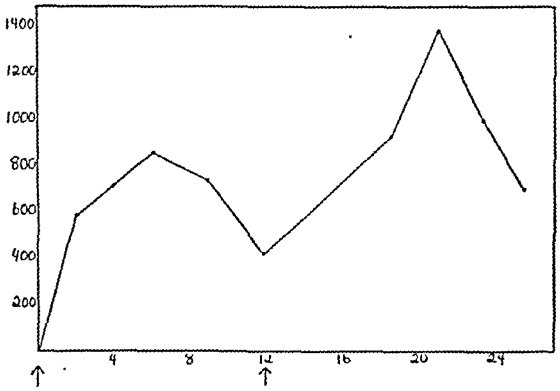

Fig. 3.—Effect of the administration of two injections of 200 mg. of heparin in 1 cc. of menstruum at twelve hour intervals. The vertical column of figures shows the coagulation time in percentage of normal, and the horizontal row shows the number of hours after the injection. The injections were given at the time indicated by the arrows.

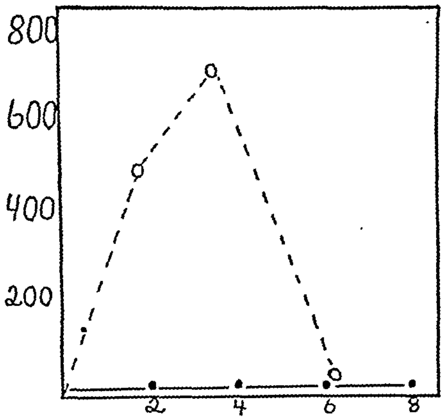

Fig. 4.—Graph of results in controls. Effect of the intramuscular injection of 200 mg. of heparin in 1 cc. of aqueous solution with no menstruum (broken line with circles) and the effect of intramuscular injection of 1 cc. of menstruum alone (broken line with dots).

---

[5] Coagulation time determination was by the Lee-White three tube method.

[6] Heparin was supplied by The Upjohn Company.

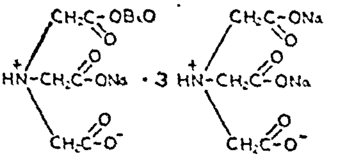
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

BISMUTH SODIUM TRIGLYCOLLAMATE.—Bistrimate-C. D. Smith.—A double salt of bismuthyl sodium triglycollamate and disodium triglycollamate containing approximately 18.3 per cent of bismuth.—$C_{24}H_{28}O_{25}N_4BiNa_7$.—F. W. 1142. The structural formula of bismuth sodium triglycollamate may be represented as follows:



Actions and Uses.—Bismuth sodium triglycollamate is designed to provide bismuth in a form effective for oral administration in the treatment of syphilis. It may be used as an adjunct with arsenicals or other agents shown to be effective in the treatment of the disease. It may be used alone in the management of certain forms of the disease, but it should not be solely relied on for curative therapy of early or active syphilitic infection. It is primarily indicated when there is intolerance to other drugs or other forms of bismuth ordinarily employed for the same purpose.

Bismuth sodium triglycollamate is subject to the same contraindications as bismuth preparations in general.

Dosage.—Bismuth sodium triglycollamate is administered orally in tablet form, usually prescribed in single doses of 0.41 Gm. (75 mg. of bismuth) two or three times daily after meals to provide a total daily dosage of from 0.82 Gm. (150 mg. of bismuth) to 1.23 Gm. (225 mg. of bismuth). The higher total daily dosage is desirable to maintain a satisfactory bismuth excretion level, but this may be temporarily reduced to the lower figure to overcome gastrointestinal disturbances that are occasionally encountered.

Tests and Standards.—

Bismuth sodium triglycollamate occurs as a white, odorless, crystalline powder with a somewhat salty taste. It is stable on exposure to air and is unaffected by light. It is very soluble in water but insoluble in organic solvents such as acetone, benzene and ether. The *p*H of a 2 per cent aqueous solution is between 7 and 8.

Add a drop of diluted hydrochloric acid to 0.1 Gm. of bismuth sodium triglycollamate: effervescence does not occur (*carbonate*). One gram of bismuth sodium triglycollamate should show no more chloride than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid (*U.S.P. XIII*, p. 709).

Dissolve 2 Gm. ot bismuth sodium triglycollamate in 15 cc. of distilled water, add 5 cc. of diluted hydrochloric acid and shake the mixture until precipitation is complete. Collect the crystalline precipitate on a filter and use the filtrate for later tests. The melting point of the washed, dried crystals is not less than 225 C. Dissolve about 0.1 Gm. of the crystalline product, accurately weighed, in 50 cc. of hot water; add 2 drops of phenolphthalein T.S., and titrate with twentieth-normal sodium hydroxide. The neutralization equivalent should be not less than 94 and not more than 97.

Add 5 drops of barium chloride T.S. to 5 cc. of the filtrate: the solution shows no more sulfate than corresponds to 0.25 cc. of fiftieth-normal sulfuric acid.

To another 5 cc. portion of the filtrate add an equal amount of sulfuric acid (*caution!*) and cool the mixture. Superimpose ferrous sulfate T. S.: no brown ring is produced at the junction of the two liquids (*nitrate*).

Ignite 3 Gm. of bismuth sodium triglycollamate in a quartz crucible, not above 700 C., cool and cautiously add, dropwise, just sufficient nitric acid to dissolve the residue when warmed. Pour the acid solution into 100 cc. of water, evaporate to 30 cc., filter and take three 5 cc. portions of the filtrate. To one portion add an equal amount of diluted sulfuric acid: the liquid does not become cloudy (*lead*). To the second portion add an excess of ammonium hydroxide: no bluish tint develops (*copper*). To the third portion add diluted hydrochloric acid: a precipitate insoluble in excess hydrochloric acid and soluble in strong ammonia solution is not formed (*silver*).

Mix 0.2 Gm. of bismuth sodium triglycollamate with 2 cc. of sulfuric acid. Heat the mixture until fumes of sulfur trioxide are evolved. Cool and dilute with water until the solution measures 5 cc. This solution meets the requirements of the test for arsenic (*U.S.P. XIII*, p. 618.).

Dry about 1.2 Gm. of bismuth sodium triglycollamate, accurately weighed, at 100 C. for two hours: the loss in weight does not exceed 2 per cent.

Ignite about 1 Gm. of dried bismuth sodium triglycollamate, accurately weighed, in a shallow porcelain crucible in a muffle furnace at 700 C. Cool, dissolve the residue with 5 cc. of hydrochloric acid and transfer the solution quantitatively to a 250 cc. beaker with 100 cc. of water. Heat it to boiling and saturate the solution with hydrogen sulfide. Collect the precipitate on a tared Jena or Gooch crucible and wash it successively with water, alcohol, ether, carbon disulfide, alcohol and ether. Dry the residue to constant weight at 100 C., cool and weigh: the bismuth content calculated from the weight of bismuth sulfide obtained is not less than 18 per cent and not more than 19 per cent.

Carroll Dunham Smith Pharmacal Company, New Brunswick, N. J.

Tablets Bistrimate: 0.41 Gm. Each tablet contains the equivalent of 75 mg. of bismuth.

U. S. patent 2,348,984.

Council on Foods and Nutrition

STATEMENT

The Council on Foods and Nutrition has long been opposed to the indiscriminate fortification of general purpose foods. Some exceptions to this rule have been recognized, however, such as the fortification of the general milk supply with 400 units of vitamin D per quart and the addition of iodine to table salt. The Council has not regarded the further fortification of the general milk supply, as is sometimes proposed, as being in the interest of public health and has so expressed itself in its regulations. Milk products which are made and sold as special purpose foods for particular groups of the population belong in a different category and are accepted on the basis of their individual merits.

At its meeting on May 8, 1948, the Food and Nutrition Board of the National Research Council prepared a statement concerning the addition of vitamins to milk which is in essential agreement with the opinion expressed by the Council on Foods and Nutrition. At its annual meeting on June 26, 1948, the Council voted to affirm the Board's opinion as expressed in the following statement.

James R. Wilson, M.D., *Secretary.*

ADDITION OF VITAMINS TO MILK

Statement of the Food and Nutrition Board, National Research Council, Adopted May 8, 1948

The Food and Nutrition Board has reviewed its previous actions concerning fortification of milk and reaffirms its decisions. In order to avoid possible misinterpretation of these decisions the following statements are intended to clarify the Board's position.

According to the decision of Dec. 2, 1944, the Food and Nutrition Board does not favor fortification of the general milk supply with minerals or vitamins other than vitamin D. The Board favors fortification of milk with vitamin D to the level of 400 U. S. P. units to the quart when the milk is used as a source of this vitamin. The Board favors fulfilment of the nutritional needs of the people by the use of ordinary foods so far as practicable. To that end it encourages education in proper choice of foods, improvement of food production, manufacture and preparation so as to increase and retain more fully the essential nutrients naturally present, and improvement in distribution so that diets adequate for health may be available to all persons.

According to the decision of July 1947, fortification of milk with vitamin A is not needed because in the United States diets adequate in vitamin A are available and fortification of milk with vitamin A is deemed unnecessary as a general public health measure.

The preceding decisions were not intended to hinder appropriate study and development of nutritionally useful new products. The Board realizes that development in technology and nutrition is rapid and does not favor restrictions which unduly handicap such progress. It did not assume and does not now intend that its decisions cited above should be interpreted as grounds for prohibiting investigation and market trials with milk modified by the addition of appropriate ingredients in reasonable amounts.

Modified forms of milk generally involve advance in price, at least during the early period of development. The Board emphasizes that wider and more uniform consumption of milk is highly desirable from the standpoint of public health, and it is particularly concerned with making available the best quality of milk at low cost.

ASEPSIS IN THE TREATMENT OF BURNS

Severe burns are frequently complicated by infection; surprisingly, however, the concept that a burn is a wound requiring the aseptic precautions ordinarily followed in the surgical management of other types of injury has been less widely recognized. Delay in acceptance of this concept of burns apparently stems from the formerly prevalent idea that infection in a burn was more or less inevitable, so that more attention has been focused on treatment than on prevention of infection. Apparently few careful investigations have been made to determine the exact sources of infection commonly contaminating burns.

Colebrook, Duncan and Ross[1] have recently drawn further attention to the causes of infection and have emphasized the need for asepsis in the local management of burns. These observers present the results of a bacteriologic study of 734 patients, including both sexes and all types of burns, during three years from 1945 to 1947. The patients were treated under conditions aimed at eliminating not only "contact" infections from hands and instruments, but also air-borne infections. They sought to determine the presence and source of infections by repeated bacteriologic examination of burn areas to discover, first, whether infection had been acquired in the hospital and, second, whether this occurred at the time of dressing the wounds ("contact" infections) or during the intervening time between dressings, i. e., air-borne cross infection from the hospital ward. Burns were dressed by aseptic surgical technic with local antiseptic agents under conditions that provided for the exclusion of air-borne infection in a specially designed room of the hospital. Care was taken to obtain perfect covering of the burns, and skin replacement was made at an early stage. By these procedures the investigators report bacteriologic evidence of hemolytic streptococcic and pyocyanic infection acquired at the time of dressing in less than 1 per cent of the patients. They point out that it has been more difficult to control cross infection occurring in the hospital wards between dressings. This was largely due to difficulty in obtaining adequate covering of the burns in areas about the face, buttocks or perineum, so that interference with the dressings by the patient led to contamination by direct contact or from air-borne dust. Another factor involves soaking of the dressing by serum exudation of the wound so that bacteria on the outside find an avenue for entrance through the dressing. Cellophane is suggested as a bacterial barrier.

In the study reported, streptococcic infections proved the easiest to control with locally applied penicillin, whereas infections by Pseudomonas aeruginosa and Staphylococcus aureus were more difficult to eliminate. The older system of admitting patients with burns to general wards of hospitals is unsatisfactory, because most of the sepsis of burns is due to preventable infection acquired in the hospital. Two objectives should be kept in view in the local management of burns: (1) blocking the transmission of pathogens at the time of dressing and (2) blocking of infection between dressings while the burns are covered. The investigators recommend that hospital facilities be provided for early isolation in all burn cases and for strict barrier nursing of all infected burns.

PORTACAVAL SHUNTS FOR PORTAL HYPERTENSION

Portal hypertension develops secondarily to partial or complete obstruction of the portal blood flow. The obstruction may be one of two types, intrahepatic or extrahepatic, or a combination of both. The site of the portal block, whether intrahepatic or extrahepatic, can usually be determined by certain tests of hepatic function. According to Whipple,[1] a high retention of sulfobromophthalein sodium in the blood thirty minutes after intravenous injection, a positive reaction to the hippuric acid test, a reversal of the albumin-globulin ratio, a positive reaction to the cephalin flocculation test, all point to the diagnosis of cirrhosis of the liver with intrahepatic portal block. If these reactions are negative, one can assume that the block is extrahepatic.

Intrahepatic block may be caused by portal cirrhosis of the Laennec type or by thrombosis of the hepatic veins, the so-called Chiari syndrome. The extrahepatic block may be congenital, the result of thrombosis of the portal vein or of one or more of its tributaries. A combination of the two main types may occur. Whipple described a form of extrahepatic block caused by cavernomatous transformation of the portal vein.

[1] Whipple, A. O.: The Problem of Portal Hypertension in Relation to the Hepatosplenopathies, Ann. Surg. 122: 449-475 (Oct.) 1945.

The syndrome of extrahepatic portal bed block described by Banti is characterized by secondary anemia, leukopenia, splenomegaly and a tendency to repeated massive gastrointestinal hemorrhages, most frequently associated with ruptured esophageal varices. The liver may be cirrhotic or may be normal, depending on the site of obstruction.

The idea of shunting portal blood into a systemic vein was conceived by Eck, a young Russian doctor working in Pavlov's laboratory. In 1877 he performed an anastomosis between the portal vein and the vena cava in a dog. The operation of diverting most of the portal blood from the liver appeared at the time too hazardous and was therefore not attempted on human beings. However, much to Eck's surprise the operation became a standard physiologic method, known as Eck's fistula, in studies of hepatic function. The dog on which Eck had performed the operation escaped from the animal house of the Military-Medical Academy (St. Petersburg), so that Eck was not able to observe the effect of the fistula. He did not occupy himself further with experimental physiology but became a popular physician in St. Petersburg.[2] Among the few successful attempts to perform a portacaval shunt in human beings are the case of Rosenstein in Germany and that of Bogoraz in Russia. Bogoraz anastomosed the superior mesenteric vein to the inferior vena cava. George Whipple[3] and his co-workers made the Eck fistula on dogs so that only the blood from the hepatic artery reached the liver. They found rather insignificant histologic changes in the liver and few functional abnormalities. The dog can tolerate the fistula from one to eight years.

The recent interest in portacaval shunts in the treatment of portacaval hypertension in human beings has resulted at least partially from the nonsuture method for blood vessel anastomosis devised by Blakemore and Lord.[4] Whipple[1] and Blakemore have carried out five splenorenal anastomoses, after removing the spleen and the left kidney, and five anastomoses of the portal vein to the inferior vena cava, end to side. All these patients have survived their operations. Blalock[5] prefers the suture method, believing that there is less likelihood of thrombosis with this method than there is in using a large foreign body such as vitallium ® tube used in the nonsuture method.

Linton[6] and his associates performed portacaval shunts in 15 patients. They feel that operation of choice should be, whenever possible, a splenectomy and the suture type of end to side splenorenal anastomosis with preservation of the kidney. They have also employed successfully anastomosis of the superior mesenteric vein to the inferior vena cava and of the inferior mesenteric vein to the left ovarian vein in 2 patients who had had the spleen previously removed. They feel that direct anastomosis of portal vein to the inferior vena cava may frequently be too hazardous because of the extreme degree of vascularity in the region of the gastrohepatic ligament.

The result of a successfully carried out portacaval shunt is to prevent serious hemorrhages from esophageal varices, to reduce portal hypertension and to improve hepatic function.

MEDICAL SCIENCE AND THE ADMINISTRATION OF JUSTICE

One of the basic principles of the political credo of the United States places on the government responsibility for administration of the law with justice and humanity. Throughout most of the United States, government fails to provide a competent investigative agency for acquiring such medical facts as may be needed to recognize the crime of murder, to apprehend and convict murderers and to protect those unjustly suspected of murder.

One death in every 5 in the United States is either known or suspected to have resulted from violence or has occurred unexpectedly from obscure causes. Each year approximately 300,000 such deaths occur. In this tremendous annual pool of criminal, suspicious and obscure deaths 13,000 murders are officially recognized —1 murder per year for every 10,000 living persons. Over 250,000 persons now alive in the United States will be the victims of homicide. Since such deaths are investigated in most places by the archaic office of county coroner, the number of murders that actually take place or the number of deaths actually due to accident, suicide or natural causes that are erroneously attributed to murder cannot be estimated.

In most states the coroner's office is so incompetent in the acquisition and interpretation of medical facts that only when murders have been witnessed or when bodies bear wounds regarded as being obviously homicidal are the deaths likely to be reported as murders.[1] In regions where competent medical investigations of such deaths are conducted, in 10 per cent to 20 per cent of all murders the crime appears to be unwitnessed and the body does not display external wounds that can be regarded as indicative of homicide. With reasonable certainty it may be said that several thousands of murders pass unrecognized each year in the United States because of the absence of a competent agency for the acquisition of medicolegal information.

[1] Report of the Committee of the American Medical Association to Study the Relationship of Medicine and Law, J. A. M. A. **125:** 577 (June 24) 1944.

Unfortunately, nonrecognition of murder is not the only danger inherent to the coroner system as it functions in most areas. Not only has the United States a greater incidence of recognized murder per unit of population than any other civilized nation in the world, but it also has the highest rate of unsolved crime. Scientific evidence which could aid in the apprehension and conviction of the criminal is rarely acquired by the average coroner's office. Recognition of evidence pertaining to the precise nature of the instrument of death, the sequence of injuries, the time of injury, the time of death, the identity of the decedent and the various traces that might associate the criminal with the crime requires a degree of expertness and experience on the part of the medical investigator that is rarely if ever found in an office administered by an elected official whose only qualification is that he or she is a registered voter of the county. Failure to acquire available information of these kinds often leads to failure to arrest, or else to false arrest, to wrongful conviction and to unduly protracted or unsuccessful prosecution.

Less important statistically but of tremendous moral importance is the fact that investigative incompetence occasionally leads to suspicion or prosecution of persons for murders that were never committed. Marks on a body that appear to the lay coroner and his jury and sometimes even to a physician inexperienced in legal medicine as evidence of criminal violence are sometimes due to misadventure or suicide. If in such circumstances there appear to be motive and opportunity for some one to have committed murder the inquest may charge some one with a crime that was never committed. Incompetent medical evidence derived from the coroner's office can only be responsible for many unfounded criminal proceedings.

A few states[2] have already established medical examiner systems, headed by a competent pathologist with experience in legal medicine and staffed by physicians within the state—these last serve on a part time basis. The function of such a system is to provide reliable facts which would not otherwise be available. The purpose of this fact finding is the ever closer approximation of law and its administration to the fullest justice. Justice can show neither fear nor favor, bias nor bigotry. It can tolerate neither ignorance nor charlatanry. In many parts of the United States the people have suffered, and are suffering, under these perversions of justice.

Current Comment

A NEW HEALTH BULLETIN

Periodicals on health for the public issued by health departments are relatively common. Similar publications by state medical societies still remain unusual. The Arizona Medical Association presents a new publication[1] entitled *Health Activities Bulletin,* published "in the interest of *your* health." This bulletin, which is a 24 page quarterly with a statewide circulation of 5,000 in 1948, is one expression of the activities of two committees created by the Arizona Medical Association in 1947. The first issue has a diversified table of contents including an article on child guidance, one on physical education, one on health in public schools and one on the public health nurse in the schools. There are a special article on infantile paralysis, a page devoted to the Woman's Auxiliary, a listing of health services available in Arizona and a scattering of short features. The entire makeup of the *Bulletin* is attractive and creditable.

ST. LUKE

October 18 was the Feast of St. Luke, who among all saints is the patron saint of physicians. In many places the day was celebrated by medical colleges and hospitals with special ceremony. Luke was referred to by St. Paul as "My beloved Luke, the physician." By strange coincidence, when William Harvey of England entered the medical school of the University of Padua in Venice in 1598, it is recorded that the academic year began on October 18 with a celebration of mass in honor of St. Luke. In a baccalaureate sermon entitled "The Beloved Physician," the Rev. John R. Cunningham, president of Davidson College, emphasized the fact that Luke was particularly concerned with the sanctity and worth of the individual. In the Book of Luke he makes it clear that to him individuals always take precedence over masses of men. The Reverend Mr. Cunningham says, "This is a fundamental principle at the heart of Christianity. It is basic in the democracy for which we now contend." St. Luke records that "when Christ at the end of a particular day was confronted with a great mass of the sick, 'He, laying His hand on every one of them, healed them.'" It was the individual with whom he was concerned rather than the mass. Without entering into any theologic discussions concerning whether or not Luke was actually a physician or actually the author of the portion of the New Testament accredited to him, he represents today the very embodiment of the highest type of physician. Those who would reduce human beings to a common entity, treat them without regard to individual humanity and spirituality, might well realize that the great majority of physicians today have learned the importance of the individual when his health and life are concerned and that that has come down to us through many hundreds of years.

ORGANIZATION SECTION

Official Notes

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

November 28-29, 1948
St. Louis, Mo.

PROGRAM

SUNDAY, NOVEMBER 28

Missouri Room, Hotel Statler

8:30 a. m. Registration.

9:30 a. m. Call to Order. Dwight L. Wilbur, San Francisco, Chairman of Program Committee.

9:35 a. m. Purposes of the Conference. George F. Lull, Chicago, Secretary and General Manager, American Medical Association.

9:40 a. m. Address of Welcome. Roscoe L. Sensenich, South Bend, Ind., President, American Medical Association.

9:50 a. m. Symposium on Medical Legislation:

From the Point of View of the Board of Trustees of the American Medical Association. Edward J. McCormick, Toledo, Ohio.

From the Point of View of a State Association. Dwight H. Murray, Napa, Calif.

From the Point of View of a Congressman. Speaker to be announced.

11:00 a. m. Symposium on Osteopathy in Its Relationship to Medicine:

William H. Halley, Denver, Delegate to American Medical Association.

George W. Covey, Lincoln, Neb., Secretary, Nebraska Medical Examining Board.

Creighton Barker, New Haven, Conn., Secretary, Connecticut Medical Examining Board.

12 M. Recess for Luncheon.

1:30 p. m. Report on Cooperative Medical Advertising Bureau. Stanley B. Weld, Hartford, Conn., Chairman, Advisory Committee, Cooperative Medical Advertising Bureau, and Alfred J. Jackson, Chicago, Director, Cooperative Medical Advertising Bureau.

1:45 p. m. Announcements.

Round Table Conferences

Room 102, Hotel Statler, 2 p. m.

CONFERENCE ON MEDICAL SOCIETY RADIO PROGRAMS

Earl Whedon, Sheridan, Wyo., Associate Editor, *Rocky Mountain Medical Journal,* Moderator

Jonathan Forman, Columbus, Ohio, Editor, *Ohio State Medical Journal,* and John F. Conlin, Boston, Director of Public Information, Massachusetts Medical Society.

Missouri Room, Hotel Statler, 2 p. m.

CONFERENCE ON MEDICAL-HOSPITAL PREPAYMENT PLANS

Peter Pineo Chase, Providence, R. I., Editor, *Rhode Island Medical Journal,* Moderator

Indemnity Plans. Carll S. Mundy, Toledo, Ohio, Chairman, Executive Committee, Ohio Medical Indemnity, Inc.

Service Plans. Robert L. Novy, Detroit, President, Michigan Medical Service.

Cooperatives. Frank Elias, Duluth, Minn.

Room 104, Hotel Statler, 2 p. m.

CONFERENCE ON MEDICAL LEGISLATION

Charles Crownhart, Madison, Wis., Secretary, State Medical Society of Wisconsin, Moderator

Edward J. McCormick, Toledo, Ohio, and Dwight H. Murray, Napa, Calif., Trustees of American Medical Association, and a speaker to be announced.

Missouri Room

6:30 p. m. Dinner for Secretaries and Editors.

8:00 p. m. State Medical Journal Clinic.

Dwight L. Wilbur, San Francisco, Chairman of Program Committee, Presiding

Journals selected for discussion are *Arizona Medicine, The Pennsylvania Medical Journal, The Journal of the South Carolina Medical Association* and the *Texas State Journal of Medicine,* the editors of which have cooperated by authorizing the study and discussion of their publications for this Conference.

Format and Typography. John Lamoreoux, St. Louis, The Warwick Press.

Editorial Content. Edwin P. Jordan, Cleveland.

Advertising Format and Makeup. Harry C. Phibbs, Chicago, Harry C. Phibbs Advertising Company.

MONDAY, NOVEMBER 29

Missouri Room

10:00 a. m. Medical and Hospital Care Prepayment Plans. Paul R. Hawley, Chicago, Chief Executive Officer, Blue Shield-Blue Cross Commissions.

10:30 a. m. Medical Care of the Nation in the Event of Another War. James C. Sargent, Milwaukee, Chairman; Council on National Emergency Medical Service, American Medical Association.

Stafford L. Warren, Los Angeles, Dean, Medical School of University of California at Los Angeles and Radiological Chief Consultant at Bikini Atomic Bomb Tests.

11:00 a. m. Ten Minute Reports by Moderators of Sunday Afternoon Conferences.

11:30 a. m. General Discussion.

12:00 Noon. Adjournment.

SOUTH CENTRAL REGIONAL CONFERENCE

Mayo Hotel, Tulsa, Okla.

Saturday and Sunday, November 13 and 14

Sponsored by the A. M. A. Council on Medical Service and

Arkansas Medical Society
Kansas Medical Society
Louisiana State Medical Society
State Medical Association of Texas

Program

SATURDAY MORNING SESSION

9:30 a. m. *Registration*

James R. McVay, M.D., Kansas City, Mo., Council on Medical Service, American Medical Association, *Chairman*

Welcome

C. E. Northcutt, M.D., President, Oklahoma State Medical Association, Ponca City, Okla.

Why Get Together?

James R. McVay, M.D.

Roundtable Discussion—*What We Expect from the American Medical Association and the Council on Medical Service*

Moderator: George A. Schenewerk, M.D., Chairman, Committee on Public Relations, State Medical Association of Texas

Discussants: From each of the state associations (5 minutes each)

Open Question and Answer Period.

Luncheon

Medical Aspects in the Next National Emergency

James C. Sargent, M.D., Milwaukee, Chairman, Council on National Emergency Medical Service, American Medical Association

SATURDAY AFTERNOON SESSION

Roundtable Discussion—*Present Day Problems*

Moderator: J. D. McCarthy, M.D., Omaha, Council on Medical Service, American Medical Association

Medical School Influence on the Practice of Medicine

Discussant (15 minutes): Franklin D. Murphy, M.D., University of Kansas Medical Center, Kansas City, Kan.

Hospital Encroachment on the Practice of Medicine

Discussant (15 minutes): Daniel J. Murphy, M.D., New Orleans

Open Question and Answer Period

Roundtable Discussion—*The National Health Assembly*

(The discussion of the National Health Assembly will include "The Ewing Report")

Moderator: James Stevenson, M.D., Tulsa, Okla.

Conflict as to Methods of Rendering Medical and Hospital Service

Discussant (10 minutes): Thomas A. Hendricks, Chicago, Secretary, Council on Medical Service, American Medical Association

Effects on Future Legislation

Discussant (10 minutes): Joseph S. Lawrence, M.D., Washington, D. C., Director, Washington Office of the Council on Medical Service

Open Question and Answer Period

SATURDAY EVENING SESSION

Dinner

Wake Up, Doctor! Wake Up!

Mr. John I. Taylor, Mountain View, Okla., President, Oklahoma Farm Bureau Federation

SUNDAY MORNING SESSION

10:00 a. m. *Rural Health Symposium*

Moderator: Allen T. Stewart, M.D., Lubbock, Texas, Committee on Rural Medical Service, American Medical Association

What Does It Take to Provide Adequate Health Care?

Rural Medical Care—The Farmer's View

The Cooperative Hospital

Establishing Local Health Units

Organizing Local Health Councils

The Medical School and Rural Practice

Reports of State Association Rural Health Committees

SUMMARY OF LEGISLATION OF INTEREST TO PHYSICIANS ENACTED BETWEEN JULY 1, 1947 AND JUNE 30, 1948

PREPARED BY GEORGE E. HALL

Bureau of Legal Medicine and Legislation

The legislatures of nine states were in regular session during the period covered by this survey. Three or four additional states held special sessions. As is usual in the "off year" of state legislation, the number of proposals considered and laws enacted were relatively small. Only a few laws specifically concern the licensing of physicians, but medical schools, medical scholarships and medical research programs received legislative approval in various forms. Activity along the line of hospital survey and construction acts was continued and a number of other general surveys planned, e. g., a survey of the conduct of the board of naturopathic examiners in South Carolina, a survey of nonprofit hospital service corporations in Massachusetts and Virginia, a survey of mental hygiene at Sing Sing Prison and a survey of the problem of alcoholism in Virginia and South Carolina. Mississippi became the forty-eighth state to enact a workmen's compensation law. Most of the proposals of interest to the medical profession have previously been briefly referred to in The Journal at the time of their introduction, passage or enactment. This survey summarizes only those which successfully withstood the legislative processes and were enacted into law.

I. ALLIED PROFESSIONS AND SUNDRY VOCATIONS

Chiropody.—Bills relating to the practice of chiropody were enacted in Kentucky, Massachusetts and New York. Kentucky[1] created a board of examiners for chiropody and defined chiropody as the diagnosis and the local, medical, mechanical and surgical treatment of ailments of the human foot, and massage in connection therewith, except amputation of the foot or toes, the use of anesthetics other than local or the use of drugs or medicine other than local. The New York[2] law concerned itself with the definition of podiatry by providing as follows: A person practices podiatry who holds himself out as being able to diagnose ailments of the human feet by mechanical, chemical and physical means and/or as being able to practice minor surgery on the feet within the following limitations: the practice of minor surgery shall not permit operations on the bones, muscles or tendons of the feet or any other part of the body except operations for minor deformities of mechanical and functional nature, including the structures superficial to the deep fascia and including all structures of the terminal phalanges. It shall confer the right to treat for disease, pain, injury and deformity of the feet, and it shall not include any other part of the body. The treatment of fractures shall be limited to simple uncomplicated fractures of the phalanges and metatarsals. The use of anesthesia shall be limited to local anesthetics for therapeutic purposes as well as for anesthesia, and the right to use non-narcotic postoperative sedatives. The Massachusetts[3] law amended the chiropody act by setting forth the procedure by which a chiropody school may obtain board approval.

Cosmetology.—Louisiana[4] and Mississippi[5] created state boards of examiners for cosmetology and cosmetic therapy and defined such practice, the Louisiana definition including "also electrolysis by the use of electricity for cosmetic purposes and not for the treatment of any disease or the practice of surgery, or for the removal of any part of the skin or body except under medical supervision."

Dentistry.—Kentucky[6] and New Jersey[7] required persons desiring to practice as dental hygienists first to obtain licenses therefor from the dental examining board. The Kentucky law further required that the dental hygienist do his work under the continuous supervision and inspection of a licensed dentist

4. La., Acts 1948, Act No. 211.
5. Miss., Laws 1948, c.——, approved April 13, introduced as H. 241.
6. Ky., Laws 1948, c. 6.
7. N. J., Laws 1948, c. 34.

and defined dental hygiene as the treatment of human teeth by removing therefrom calcareous deposits and by removing accumulated accretion from directly beneath the free margin of the gums and by polishing the exposed surface of the teeth and by making roentgenograms of teeth and surrounding tissues. An Alabama[8] law enacted last year, but too late to be included in the 1947 survey, provided for the creation and establishment of a four year school of dentistry in the state. Louisiana[9] provided that no member of the faculty or teaching staff of any university or college having a dental department in the state and no dentist owning stock or operating a dental supply business or commercial laboratory is eligible for appointment to the state board of dentistry. One Massachusetts[10] law provided that no corporation could conduct a dental office and that no person could conduct a dental office under any name other than that of the dentist actually owning the practice; another[11] increased the penalty for the illegal practice of dentistry. Mississippi[12] provided for gubernatorial appointments to the State Board of Dental Examiners from a list submitted by the Mississippi Dental Association. A Massachusetts[13] resolution provided for a survey of laws relating to the practice of dentistry by an unpaid commission to report back to the clerk of the house of representatives during December of 1948.

Nursing.—Louisiana,[14] New York[15] and Rhode Island[16] enacted laws providing for the licensing and regulating of practical nurses. The Louisiana law defined practical nursing as the performance of nursing services for patients, wherein the practical nurse is at all times under the supervision and direction of a licensed physician or a registered nurse acting under the supervision of a licensed physician. Two New York[17] laws authorized the licensing without examination of graduates of accredited nursing schools from other states under certain conditions. Three Mississippi[18] laws created scholarships for students of nursing. One[18a] of them authorized the establishment of a scholarship program for the advanced study of nursing to consist of forty scholarships of the value of not more than $3,000 each and provided that students accepting assistance from these scholarships be required to spend a period of time nursing in the state of Mississippi equal to the number of years during which they accepted the benefits of the scholarships. Another[18b] granted an appropriation to the board of trustees of state institutions of higher learning of $120,000 for the purpose of setting up scholarships for advanced studies in nursing. The third[18c] authorized the establishment of a school of nursing at the University of Mississippi and the inauguration of a scholarship program in connection therewith. Still another Mississippi[19] law amended the law relating to the Mississippi Commission on Hospital Care by, among other things, authorizing it to lay out a plan for building and equipping schools of nursing to be located in strategic points in the state for the promotion of the advancement of nursing education. A Virginia[20] law authorized the governing boards of the Medical College of Virginia and of the University of Virginia each to establish thirty-five nursing scholarships of the annual value of $100 each. A Massachusetts[21] law reduced the age limit of applicants for admission to nursing schools from 21 to 20 years. A Mississippi[22] law amended the Mississippi code relating to registered nurses by clarifying the powers and duties of the board of nurses' examiners. A Louisiana[23] law provided for the establishment and operation of a psychiatric training course for student nurses in the Central Louisiana State Hospital.

Optometry.—South Carolina[24] provided general amendments to the optometry act, including, among other things, a provision that no optometrist may use the title Doctor unless he has actually received a degree from a duly authorized college.

Pharmacy.—Massachusetts[25] authorized the Boston School of Pharmacy to issue the Bachelor of Science in Pharmacy degree after meeting certain requirements. Mississippi[26] prohibited the operation of any drugstore or pharmacy unless the owner or operator be, or shall have in his regular employ, a registered pharmacist or a licensed physician on duty. Mississippi[27] also required all persons licensed to practice pharmacy to renew their licenses annually. Louisiana[28] enacted a law regulating, defining and controlling the practice of pharmacy, and Virginia[29] enacted general amendments to the pharmacy law relating to the sale and inspection of drugs.

II. DISEASE CONTROL AND PUBLIC HEALTH MATTERS

General Public Health Programs.—Louisiana[30] provided an appropriation to the state board of health to prevent any decrease in the public health programs initiated within the state. South Carolina[31] enacted a resolution directing the executive committee of the Board of Health to make a careful investigation of the allocation of funds to the different counties for county health work and to adopt a plan which would distribute such funds equitably.

School Health Programs.—Louisiana,[32] Massachusetts,[33] Mississippi,[34] New York[35] and Virginia[36] enacted legislation designed to facilitate the operation of the National School Lunch Act. Mississippi[37] also provided an appropriation for assistance in carrying out a program of coordinated school, health and nutrition services in cooperation with the international health division of the Rockefeller Foundation and the general education board. A Massachusetts[38] law authorized the school committee of the city of Boston to make appropriations for organizing and conducting physical training and exercises, athletics, games and the like under the control of the committee and authorized the payment by insurance or otherwise of the reasonable hospital, medical and surgical expenses incurred by or in behalf of any student who sustains injuries while participating in any of the organized school athletics.

State Facilitcis for Tuberculosis Diagnosis and Control.—Kentucky[39] and Louisiana[40] created state tuberculosis sanatorium commissions in their respective states. Arizona[41] provided an appropriation to the state department of health to assist in remodeling buildings and in purchasing and installing surgical and x-ray equipment at the existing state tuberculosis sanatorium. New Jersey[42] and South Carolina[43] enacted laws authorizing the commitment to county hospitals or sanatoriums of persons who fail to obey rules and regulations concerning the prevention or spread of tuberculosis so as to restrain such persons from being a menace to their household or community. A New York[44] law amended the public health law by providing that no vaccine shall be used for the purpose of inducing immunity against tuberculosis unless it has been produced in accordance with regulations established or approved by the state commissioner of health.

Venereal Disease Appropriations for Eradication.—Two Mississippi[45] laws provided appropriations to defray the expenses of the state program for the eradication and control of syphilis and other venereal diseases. A third Mississippi[46] law provided an appropriation for the treatment of neurosyphilis and other diseases leading to insanity.

Miscellaneous.—Mississippi[47] required the state building commission to establish facilities for the treatment of alcoholics and narcotic addicts.

III. FOODS, DRUGS, COSMETICS AND THERAPEUTIC DEVICES

Aminopyrine, Sulfonamide Barbiturates and Other "Dangerous Drugs."—South Carolina[48] put sulfanilamide, sulfathiazole, sulfapyridine, sulfadiazine, aminopyrine, thyroid and other antifat preparations, together with any other drugs declared to be "dangerous drugs," on a prescription basis. Massachusetts[49] amended and reenacted the law relative to adulteration and misbranding of dangerous drugs by providing, among other things, that no person shall sell or offer for sale at retail any harmful drug other than to a physician, dentist or veterinarian, except on the written prescription of a physician, dentist or veterinarian. "Harmful drug" is defined by the act as including amidopyrine, amphetamine, desoxyephedrine, cantharides, cinchophen, digitalis, cinitrocresol, dinitrophenol, ergot, estrogen, barbituric acid, chloral hydrate, paraldehyde, thyroid, pituitary, croton oil, oil of pennyroyal, oil of savin, oil of tansy and any other drug deemed by the department of public health to be a harmful drug.

Narcotics.—Louisiana,[50] Massachusetts[51] and New Jersey[52] enacted amendments to the narcotic laws of those states. The Louisiana law added marijuana to the regulations covered by the narcotic drug act and also adds provisions relating to the definition and punishment of narcotic addicts. The Massachusetts law prohibited the refilling of prescriptions for narcotic drugs. The New Jersey law added amidone (methadone) to the definition of "narcotic drugs."

IV. HOSPITALS

State Hospital Construction Programs.—Alabama[53] and Kentucky[54] enacted hospital construction acts. The Alabama law enacted last year, but too late to be included in the 1947 survey, was for the purpose of providing funds to the State Board of Health for the planning and constructing of state-owned and other public and nonprofit hospitals in the state. The Kentucky law provided for the creation and establishment of a "Division of Medical Hospitals and related services" in the Department of Health to make a survey of hospital facilities throughout the state and to accept federal funds to assist in the construction of additional needed facilities. This law required the appointment of an advisory council and the preparation of necessary regulations and standards pertaining to the conduct and operation of hospitals constructed by virtue of the act. Another Kentucky[55] law more or less supplemented this act by creating a Kentucky Building Commission to have charge of buildings constructed throughout the state and by providing an appropriation to this commission to be used for matching funds for hospital construction under any law now existing or that may be passed by the national congress. Two Mississippi[56] laws amended the 1946 hospital survey and construction act. One[56a] included nonprofit hospitals and facilities among those organizations eligible for grants in aid; the other[56b] authorized the operation and equipping of health centers or health departments in the various municipalities of the state. Two other Mississippi[57] laws provided appropriations to the Mississippi Commission on Hospital Care for the purpose of building, erecting and equipping hospitals and other facilities in the state. New York[58] extended the life of the Joint Hospital Survey and Planning Commission to April 1, 1949, and provided for the submission by the commission of an interim report on or before April 1, 1948. Virginia[59] provided regulations for the operation of a hospital construction fund to accept and dispense funds for the state hospital construction program. Mississippi[60] authorized an appropriation of $1,500,000 for the construction and equipping of a teaching hospital in the School of Medicine of the University of Mississippi, and South Carolina[61] provided that the Medical College of South Carolina could participate in federal funds made available to assist it in financing the construction and equipment of a teaching hospital.

Hospital Districts.—Louisiana[62] authorized adjoining parishes to create hospital service districts to provide better hospital service therein.

Liability for Taxes.—An Alabama[63] law enacted last year but too late to be included in the 1947 survey, amended the law relating to exemptions from ad valorem taxes by adding to such exempt properties all property, real or personal, used exclusively for hospital purposes, to the amount of $20,000, where such hospitals maintain wards for charity patients and subject to a few other conditions.

Licensing Requirements.—Institutional licensing laws were enacted in a number of states. Wyoming[64] required all hospitals, nursing homes, sanatoriums and the like to obtain a license from the Department of Public Health and authorized such department to make the necessary rules and regulations relative thereto. A Mississippi[65] law, referring just to hospitals, provided for the appointment of an advisory hospital council to consult and advise with the licensing agency and to assist in the development of rules, regulations and standards to be required of the hospitals seeking licensure. This law further provided that no rules, regulations or standards shall be adopted or enforced which would have the effect of denying a license to a hospital or other institution required to be licensed hereunder, solely by reason of the school or system of practice employed or permitted to be employed therein. Rhode Island[66] made certain amendments to the existing hospital licensing law, among which was a definition of a hospital as "an institution for the lodging, care and treatment of persons suffering from disease or other abnormal physical or mental conditions." This law exempted convalescent homes from its operations and provided that no person could obtain medical or surgical treatment under false representations as to his financial condition from any hospital, outpatient department or dispensary licensed by the hospital licensing law. Massachusetts[67] and Rhode Island[68] provided for the licensing, regulating and inspecting of homes for aged or convalescent persons, the Massachusetts law also applying to hospitals and sanatoriums. South Carolina[69] amended the existing hospital licensing law by granting to institutions three years within which to comply with the rules, regulations and minimum standards provided for therein.

State Hospitals.—A Louisiana[70] concurrent resolution urged the superintendents of the state's general hospitals to make every possible effort to provide facilities for at least a limited number of chronically ill patients who may need hospitalization, surgery or other medical treatment and whose lives may be made more endurable by such treatment. Louisiana[71] also created a state hospital for the care and treatment of mentally ill persons.

V. REGULATION OF HEALING ARTS PRACTICE

Annual Registration.—Virginia[72] required the annual renewal of certificates to practice medicine, homeopathy, osteopathy, chiropractic, naturopathy or chiropody on or before June 30 of each year.

[70] La., Acts 1948, c.——, adopted June 1, introduced as S. Con. Res. 10.

[71] La., Acts 1948, Act No. 238.

[72] Va., Laws 1948, c. 491.

Corporate Practice.—Virginia[73] made it unlawful for any physician, dentist or optometrist to practice his profession as a lessee of any commercial or mercantile establishment or to advertise, either in person or through any commercial or mercantile establishment, that he is a duly registered practitioner and is practicing or will practice medicine, dentistry or optometry as a lessee of such commercial or mercantile establishment.

Psychologists.—Kentucky[74] provided for the creation of a board of examiners for the certification of clinical psychologists.

Exemptions from Medical Practice Acts.—New York[75] amended the education law by providing that after July 1, 1949, medical students performing clinical clerkships or similar functions in a legally incorporated hospital shall be exempt from the provisions of the medical practice act. Virginia[76] amended the medical practice act by, among other things, exempting therefrom interns and residents in legally established and licensed hospitals provided their practice is confined strictly to persons who are bona fide patients within the hospital or who receive treatment and advice in an organized outpatient department of the hospital to which ambulant patients regularly come for professional services rendered under supervision of licensed members of the hospital staff. The law also provided, however, that such interns and residents must have completed successfully the preliminary academic education required for admission to examinations given by the board in his particular field of practice or hold a valid license issued in a state maintaining standards acceptable for reciprocity with the state of Virginia. No graduate of a substandard medical school could be so employed except under particular cases.

Causes for Revocation of Licenses.—Massachusetts[77] amended its medical practice act by providing for the revocation of the certificate of registration of any physician guilty of the use of narcotic drugs in any way other than for therapeutic purposes. Virginia[78] amended the medical practice act by authorizing the state board of medical examiners to suspend or revoke the certificate of a physician who has been the legally responsible head of a hospital the license of which has been revoked because of illegal practice or conduct or practices detrimental to the welfare of a patient therein by the state board of health.

VI. RIGHTS AND PRIVILEGES, DUTIES AND LIABILITIES OF PRACTITIONERS

Special Privilege (Offices Which Must Be Held by Physicians).—Mississippi[79] amended the law relating to the procedure for committing persons to state mental institutions by providing that no person shall be admitted to a state mental institution except on a satisfactory report from two reputable licensed physicians. Another Mississippi[80] law provided that the executive officer of the state board of health shall be a physician versed in bacteriology, hygiene and sanitary science and otherwise fitted and equipped to execute the duties incumbent on him by law and who shall not engage in the practice of medicine.

Occupational Taxes.—A Virginia[81] law required every practicing medical doctor to obtain a revenue license; a Kentucky[82] law authorized certain class cities to provide license fees for the practice of any profession.

VII. MEDICAL AND HOSPITAL SERVICE PLANS, ETC.

Prepaid Hospital Care Plans.—Louisiana[83] declared businesses organized under the insurance laws and engaged exclusively in the business of furnishing hospital service, medical or surgical benefits to subscribers to be charitable and beneficial institutions and exempt from any form of taxation. Such institutions, however, must pay an annual license fee of $250.

Prepaid Medical Care Plans.—Mississippi[84] and South Carolina[85] enacted laws providing for the organization of medical service corporations. The Mississippi law was an enabling act for the organization and operation of nonprofit hospital, medical and surgical service corporations. The South Carolina law provided for the chartering and method of organization and operation of nonprofit medical service plans furnishing medical service by physicians at the expense of the corporation to subscribers to the plan. Medical service is defined to include all general and special medical services ordinarily provided by licensed physicians in accordance with the accepted practices of the community at the time the service is rendered. Physician is defined as any physician duly licensed to practice medicine in the state of South Carolina under the provisions of the medical practice act. Massachusetts[86] authorized medical service corporations to contract with hospital service corporations for the joint or cooperative administration of their affairs.

Accident and Sickness Insurance.—New Jersey[87] enacted a temporary disability benefits law.

Government Assistance to Municipal Employees and Indigents.—Mississippi[88] provided that certain municipalities in the state may pay out of the general fund of the municipality reasonable hospital and medical expenses of any member of the fire or police department on account of occupational diseases or accidents sustained by such member in the discharge of his duties. A Louisiana[89] concurrent resolution directed the Department of Institutions to take appropriate action to provide better hospital facilities for the indigent sick, to consider the installation of adequate free ambulance service and to consider the establishment in private hospitals of charity beds on a contractual basis. A Louisiana[90] law provided an appropriation to the Department of Institutions for the purpose of purchasing ambulances, maintaining adequate free ambulance service for state hospitals and paying for charity beds in rural areas for the hospitalization of indigents. Another Louisiana[91] law resulted in the creation of a state hospital board to contract or enter into agreements with privately owned hospitals and other institutions for the care and treatment of indigent or destitute sick persons. At least two members of the board must be capable and reputable physicians engaged in the general practice of medicine in the state. New Jersey[92] authorized municipalities having no municipal hospital to make appropriations each year to be applied to the purpose of paying the cost of supporting and maintaining indigent patients in hospitals in the municipality supported by private charity.

Miscellaneous.—Massachusetts[93] authorized the commissioner of the state police to pay the reasonable hospital, medical and surgical expenses incurred by any officer disabled while on duty.

VIII. WORKMEN'S COMPENSATION AND OCCUPATIONAL DISEASE LEGISLATION

Occupational Diseases.—Virginia[94] amended the occupational disease law by including pneumoconiosis within the list of occupational diseases covered by the act.

Extent of Medical, Hospital, Dental and Other Care.—Massachusetts[95] provided that medical services shall be made available to an injured employee as long as they are necessary, regardless of the fact that maximum compensation under other sections of the law might have been paid.

Miscellaneous (Completely New Acts, etc.).—Mississippi[96] enacted a new workmen's compensation law for the state, the forty-eighth state to enact such legislation. It provided for compulsory coverage, unlimited medical care, second injury fund and double compensation for minors injured while illegally employed.

MISCELLANEOUS LEGISLATION

Ambulance Calls.—Louisiana[97] provided regulations for the selling of ambulance insurance policies. Massachusetts[98] provided for the exemption from the requirements of the compulsory motor vehicle liability insurance law of ambulances owned and operated by hospitals or other institutions supported wholly or in part by public or private donations for charitable purposes.

[96] Miss., Laws 1948, c.——, approved April 13, introduced as H. 351.
[97] La., Acts 1948, Act No. 458.
[98] Mass., Laws 1948, c. 572.

Animal Experimentation.—A Kentucky[82] law relating to license taxes in certain cities in the state, authorized the board of aldermen to provide license fees for the using, holding or exhibiting of any animal. Massachusetts[99] provided for the creation of a special commission to consider the advisability of licensing institutions capable of intelligent experimentation and of providing for supplying to licensed institutions unclaimed and unwanted animals which are held in public pounds. This commission is to investigate relative to the procurement and treatment of animals for medical experimentation and study.

Anti-Discrimination.—A number of proposals were considered in the legislatures which were intended to prohibit or prevent certain types of discrimination in connection with medical and hospital practice, but only two of these proposals were finally enacted. A Kentucky[100] law, relating to the training of Negro nurses and doctors, provided that any hospital may give instruction in nursing, medicine, surgery or other related courses of graduate grade or on the professional level, to Negroes if the governing body of the hospital, by a majority vote of its members, so elects. A New York[101] law amended the education law in relation to complaints against educational institutions for alleged discrimination in the admission of applicants.

Blood Plasma.—New York[102] amended the law relating to persons, firms and corporations procuring blood donors so as to eliminate the requirement that donors present a satisfactory physical examination certificate showing freedom from communicable disease.

Clinics and Dispensaries; Regulation.—Louisiana[103] provided an appropriation to the Louisiana State Board of Health to be used to match federal and local funds to provide for the construction and equipping of public health centers, including administrative offices, laboratories and clinics. Massachusetts[104] authorized the construction of a Springfield Municipal Hospital for the reception of persons having diseases dangerous to the public health, as a tuberculosis dispensary, as a hospital for the chronic sick, as a dental, medical and health clinic and as an infirmary for persons in need.

Departments or Boards of Health.—An Arizona[105] law created the office of director of the State Department of Public Health and set forth the eligibility requirements thereof, among which requirements are that the applicant must be a reputable physician licensed to practice in Arizona and a graduate of a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association. A Massachusetts[106] law increased the scope of the survey and study by the special commission studying and revising the laws relating to public welfare.

Divorce.—New York[107] amended the domestic relations law by providing that in actions to annul a marriage on the ground of insanity, the testimony of a physician attached to a state hospital in the department of mental hygiene who attended the patient in a professional capacity at such hospital, shall be taken.

Health Centers.—Missouri[108] authorized counties to levy a tax for the purpose of operating or maintaining public county health centers or institutions therein. A Virginia[109] law authorized the appropriation by certain municipalities of funds for the operation and maintenance of hospitals or health centers.

Medical Research Programs.—Kentucky[110] provided for the creation of a medical research commission to inaugurate a program of research in the fields of medicine, surgery and allied sciences, preventive medicine, control of diseases and all other features of medicine and surgery that affect the health and welfare of the people of the state. Massachusetts[111] enacted a resolution memorializing the Congress to enact legislation providing for the establishment of a National Science Foundation with the appropriation of sufficient funds to encourage scientific research to be conducted which shall be made available to the directors of the armed forces and insure national security in the future.

Medical Schools and Scholarships.—Massachusetts, New York, South Carolina and Virginia enacted legislation pertaining to medical education. Massachusetts[112] provided for the inspection of colleges, universities and medical schools approved for the purpose of medical education and for the withdrawal of such approval in certain instances. One New York[113] law provided for the merger and consolidation into New York University of New York corporations authorized to establish, maintain or operate any hospital, infirmary, dispensary or clinic; another[114] provided for the establishment of a state university and directed such state university to formulate plans and make recommendations for the establishment of two health and medical centers as a part thereof. South Carolina[115] authorized the acquisition of land for a site for a teaching hospital in the city of Charleston for use by the Medical College of South Carolina. The Virginia[116] law resulted in the creation of a committee to study medical education in general in the state and the relation of medical education to the services that it renders to the people. A New York[117] law amended a recent law providing for the creation of a state university by, among other things, authorizing state aid to medical schools, research centers and similar institutions or facilities operating specified training or research programs or projects pursuant to contracts with the state university. Another New York[118] law amended a previous law creating a temporary state commission to examine into the need for the creation of another state university by requiring such commission to make a report to the governor on or before May 1, 1948. A South Carolina[119] law is a joint resolution giving legislative approval to a compact entered into by the states of South Carolina, Georgia, Florida, Alabama, Tennessee and other Southern states relative to the planning, acquisition, establishment and maintenance of jointly owned and operated regional educational institutions, among which is the Meharry Medical College of Nashville, Tenn. Mississippi,[120] South Carolina[121] and Virginia[122] enacted laws relating to medical or nursing scholarships. The Mississippi law provided for the appropriation of $510,000 to the state medical education board for the purpose of carrying out the provisions of the existing law relating to medical scholarships and loans. South Carolina provided for the establishment of eight scholarships at the Medical College of the State of South Carolina of the value of $75 per month plus tuition, conditioned on the recipient doing private general medical practice during one calendar year for each year of the scholarship in some rural community in the state designated by the State Board of Health. Virginia provided amendments to and reenactments of the law setting up annual medical scholarships at the Medical College of Virginia and the University of Virginia.

Mental Health Acts.—Rhode Island[123] provided for an act to extend and strengthen the mental health services in the state and designated the State Department of Social Welfare as the agency to cooperate with the federal government in this regard.

Physical Examinations.—Louisiana[124] prohibited employers from charging employees and job applicants for medical examinations or records when required by the employer as a condition of employment. Two Alabama[125] laws were enacted in 1947,

but too late to be included in the 1947 survey. One [125a] of them amended the law relating to blood testing for syphilis by providing that every person between the ages of 14 and 50 residing or living in the state shall have his blood examined for syphilis by an approved laboratory test at such time as shall be designated by the State Board of Health. The other [125b] required that all persons between the ages of 13 and 50 residing in the state have physical and roentgenographic examinations or be otherwise tested for tuberculosis during such periods or at such times as may be designated by the State Board of Health. This law further provided that if one member of a family shows a positive reaction to the test all other members of that family regardless of age shall be subject to the examination. Rhode Island [126] authorized every superintendent of schools to cause such further examinations to be made of school children as he shall deem necessary for the purpose of guarding against any further outbreaks of infantile paralysis within the schools of any city or town. Such examinations could include examinations of the legs and pedal extremities of such children by physicians, school nurses or persons qualified to make such examinations. New York [127] amended the law relating to the state athletic commission by creating in such commission a medical advisory board to prepare and submit to the commission for approval regulations and standards for the physical examination of professional boxers and wrestlers.

Surveys.—South Carolina [128] directed the Board of Naturopathic Examiners of the state to undertake immediately a study of the various licenses and personal qualifications of applicants heretofore licensed to practice naturopathy in the state and the propriety of cancelling any licenses erroneously obtained. The board was further directed to cancel immediately any licenses of licensees to practice naturopathy if the board in its discretion decided that the license should be cancelled for any reason, and in checking the qualifications of the licensees the board should take into consideration the information developed by the Law Enforcement Division of the state of South Carolina and such other information as the Law Enforcement Division may be able to obtain with reference thereto. The Board of Naturopathic Examiners was directed to submit to the General Assembly of South Carolina in 1949 a full and complete written report concerning the matter. A New York [129] resolution continued the special joint legislative committee making a survey and study of the social, educational and physical problems of persons afflicted with cerebral palsy. Louisiana [130] provided for the appointment of a commission to develop the facts and figures in relation to and a program for the rehabilitation of alcoholics. South Carolina [131] established a special committee for the purpose of studying and making an investigation into the need and feasibility of establishing an institution, either separately or in connection with any existing state institution, for the purpose of treating chronic alcoholics. Virginia [132] created within the Department of Health a division of alcohol studies and rehabilitation for the study of the problems of alcoholism, the treatment and rehabilitation of persons addicted to the excessive use of alcoholic beverages and the promotion of preventive and educational programs. Massachusetts [133] created a special commission to make a study of the subject of nonprofit hospital service corporations. Virginia [134] directed its advisory legislative council to make a thorough study of the methods and practices of corporations and associations engaged in furnishing hospital and medical service on the prepayment plan. Arizona [135] enacted a hospital survey and construction act for the purpose of conducting a survey of existing hospital facilities and a construction program for the building of additional needed facilities. The law provides for the appointment of an advisory survey and construction council, one member of which shall be chosen from a panel of four submitted by the Arizona medical association and another member of which shall be chosen from a panel of four submitted by the Arizona society of osteopathic physicians and surgeons. Louisiana [136] granted an appropriation to the state hospital board for conducting a hospital survey and construction program and a mental health program in the state of Louisiana. Michigan [137] amended the existing hospital survey and construction act by providing that any hospital receiving federal aid under the federal hospital survey and construction act shall comply with the minimum standards of maintenance and operation which the State Department of Public Health with the advice of the advisory hospital council shall promulgate. A Louisiana [138] resolution directed the Committee on Charitable Institutions to visit any and all of the charitable and eleemosynary institutions in the state and to make any necessary recommendations which it deems appropriate. A Louisiana [139] law resulted in the enactment of a Louisiana Health and Hospital Planning Act. This act authorized the State Hospital Board to adopt a construction program within the state and to prescribe minimum standards of maintenance and operation of hospitals which receive state or federal aid. It also required the appointment of a state advisory council and the adoption of a state mental health plan in cooperation with the national mental health act. New Jersey [140] created a commission to make a survey of all voluntary charitable hospitals throughout the state to determine what steps can be taken to relieve existing overcrowding and to furnish additional revenue for operating costs to relieve the burden now being carried by the voluntary charitable hospitals. A Massachusetts [141] law required the committee on insurance to make an investigation of the desirability or necessity of revising, recodifying and recommending any changes in and additions or amendments to the laws relating to group life insurance and group accident and health insurance. Another Massachusetts [142] law provided for a special commission to study and investigate relative to preventable diseases and to the establishment of full time local health units throughout the commonwealth. New York [143] created a commission to make a study of correction and mental hygiene at Sing Sing prison to develop information as to the underlying causes of sex crimes and the development of treatment for persons committing such crimes.

Miscellaneous.—An Alabama [144] law enacted in 1947, but too late to be included in the 1947 survey, amended the law relating to the state income taxes by authorizing individual income taxpayers a deduction of expenses paid during the taxable year, not compensated for by insurance or otherwise, for medical care of the taxpayer, his spouse or his dependents to the extent that such expense exceeds 5 per cent of the gross income of the taxpayer. A Maryland [145] law exempted from the retail sales tax act the sales of crutches, artificial limbs, artificial eyes, artificial hearing devices and corrective eyeglasses, when they are designed to be worn on the person of the owner or user, and the sales of orthopedic appliances and wheelchairs. Mississippi [146] authorized the incorporation of organizations for medical and surgical purposes or for establishing, maintaining and operating clinical, pathologic, medical or surgical research laboratories or the like. South Carolina [147] authorized any department, commission, board or officer of the state to have microfilms made of any part of its records and provides that microphotographs or microphotostatic copies of such records may be introduced in evidence in any court of law in the state to the same extent as the original records would have been. A Virginia [148] law named the State Corporation Commission as an agency to require reports, estimates, facts and other data from those agencies operating on a statewide basis that exist primarily for the solicitation of funds from the public for medical care or medical research.

Washington Letter

(From a Special Correspondent)

Nov. 3, 1948.

Committee on Growth Re-Formed

Dr. Milton C. Winternitz, professor of pathology at Yale University School of Medicine, has been appointed chairman of the Committee on Growth, National Research Council (Division of Medical Sciences). He succeeds Dr. C. P. Rhoads, director of Memorial Hospital (New York City), who remains a member of the committee. As reconstituted for 1948-1949, the Committee on Growth has added several experts to its various scientific panels, and two of its six sections have new chairmen. They are Dr. Arnold D. Welch, Western Reserve University School of Medicine, for chemotherapy, and Dr. Willard M. Allen, Washington University School of Medicine, for clinical investigations. They succeed Drs. Perrin H. Long (Johns Hopkins) and Allan T. Kenyon (University of Chicago), respectively.

American Legion Publishes "Medical Advisors Manual"

Just published by American Legion offices in Washington is the "Medical Advisors Manual," a 96 page booklet designed to guide and aid physicians who are concerned with veterans' medical problems. It includes special articles by Drs. Charles W. Mayo ("Medical Education"), Winfred Overholser ("Post War Trends in Psychiatry"), Howard A. Rusk ("Medical Rehabilitation"), Waltman Walters and John V. Triolo ("War and Post War Surgery") and C. Raymond Wells ("Dentistry").

In the booklet's introduction, Dr. Leonard G. Rowntree, chairman of the Legion's National Medical Advisory Board, writes: "With its nationwide network of medical advisors, the American Legion is in a better position than ever before to become the champion of the health of the people and to elevate the national health to a higher plane than ever in the past. As medical advisors to the American Legion, it is our bounden duty to keep the medical service for the veteran at its peak and also to aid the American Legion, and the American Medical Association, in their national campaign for improvement in physical and mental health."

Nuclear Science Abstracts

Schools, hospitals, laboratories and other institutions interested in atomic medicine should take note of the fact that the publication *Atomic Energy in Biophysics, Biology and Medicine* has been succeeded by a semimonthly special edition of *Nuclear Science Abstracts,* also published by Atomic Energy Commission. First issue (vol. 1, no. 6) of the new publication made its appearance earlier this month, carrying such subject categories as Biological Effects of Radiation, Health Protection, Radiotherapy and Tracer Applications. The volume, and those which will follow at semimonthly intervals, contains abstracts of declassified AEC reports and articles pertaining to atomic energy which have been published in domestic and foreign literature.

Nuclear Science Abstracts, as well as AEC declassified documents, are available for sale by Document Sales Agency, P. O. Box 62, Oak Ridge, Tenn.

Medical Advisers Seek Over-All National Health Policy

National Security Resources Board, in a statement issued following the first meeting of its medical advisory committee on September 25, announced that NSRB Chairman Arthur M. Hill had been urged by the group to assume administration of "an over-all national health policy." Both military and civilian medical problems, with particular reference to situations that might arise in event of war, were discussed by the advisory group, whose chairman is Dr. James A. Crabtree, director of the board's medical division. Members of the committee are Drs. William P. Shepard, San Francisco; A. C. Bachmeyer, Chicago; James C. Sargent, Milwaukee; Edward L. Bortz, Philadelphia; Michael E. DeBakey, New Orleans, and Percy T. Phillips, New York.

Professional Leaders Invited to Military

Representatives of American medicine are expected to be among the professional, clerical, labor, educational, press and industrial leaders who will attend an unusual conference, announced by Secretary of Defense James Forrestal, scheduled to open in the Capital November 8. Its purpose will be to familiarize the public with attainments of the military establishment since Army, Navy and Air Force were integrated last year under Secretary Forrestal. From November 8 to 12, the conferees will meet in closed sessions to hear addresses by him, the three Department Secretaries and top ranking officials, both military and civilian, of the National Military Establishment. Then they will be flown to observe two day field demonstrations by Army, Navy and Air Force. These will be conducted, respectively, at Fort Benning, Ga., and the Pensacola and Eglin air bases in Florida.

International Medical Conferences

The year 1948, which has been the biggest postwar year for international conferences, will witness several important medical gatherings during its last quarter, according to a list compiled by the Department of State. Earlier this month conferences of the Pan American Sanitary Organization opened in Mexico City, coincident with the sixth meeting of health directors of the twenty-one American Republics. On October 15 the World Health Organization's Expert Committee on Venereal Disease will convene in Paris. The Fifth Inter-American Congress of Surgery opens in La Paz, Bolivia, October 17. Eight days later the executive board of World Health Organization will meet in Geneva. November conferences include the Second Inter-American Congress on Brucellosis at Mendoza, Argentina. December 1-8 will witness the First Pan American Congress of Pharmacy at Havana, Cuba.

Coming Medical Meetings

American Medical Association Interim Session, St. Louis, Municipal Auditorium, Nov. 30-Dec. 3. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Conference of State Secretaries and Editors, St. Louis, Hotel Statler, Nov. 28-29. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

National Medical Public Relations Conference, St. Louis, Hotel Statler, Nov. 27. Mr. Lawrence W. Rember, 535 N. Dearborn St., Chicago 10, Director.

American Academy of Dermatology and Syphilology, Chicago, Palmer House, Dec. 5-9. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, Secretary.

American Academy of Pediatrics, Atlantic City, Chalfonte-Haddon Hall, Nov. 20-23. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American Association of Railway Surgeons, Chicago, Nov. 21-23. Dr. Raymond B. Kepner, 547 W. Jackson Blvd., Chicago 6, Secretary.

American Clinical and Climatological Association, Hot Springs, Va., The Homestead, Nov. 8-10. Dr. James Bordley III, Bassett Hospital, Cooperstown, N. Y., Secretary.

American Public Health Association, Boston, Nov. 8-12. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

Association for Research in Nervous and Mental Diseases, New York, Waldorf-Astoria Hotel, Dec. 10-11. Dr. Clarence C. Hare, 700 W. 168th St., New York 32, Secretary.

Association of Military Surgeons of the United States, San Antonio, Texas, Nov. 11-13. Dr. James M. Phalen, Army Institute of Pathology, Washington 25, D. C., Secretary.

Eastern Section, American Federation for Clinical Research, Philadelphia, Temple University School of Medicine, Dec. 4. Dr. J. Edward Berk, Temple University School of Medicine, Philadelphia, Chairman.

International College of Surgeons, U. S. Chapter, St. Louis, Kiel Auditorium, Nov. 16-19. Mr. Ralph E. Osborne, 1516 Lake Shore Drive, Chicago, Business Secretary.

Inter-State Postgraduate Medical Association of North America, International Medical Assembly, Cleveland, Public Auditorium, Nov. 9-12. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.

Puerto Rico, Medical Association of, Santurce, Dec. 10-12. Dr. J. Basora Defillo, Box 3866, Santurce, Secretary.

Radiological Society of North America, San Francisco, Dec. 5-10. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Southern Psychiatric Association, Dallas, Texas, Hotel Adolphus, Dec. 6-7. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southern Surgical Association, White Sulphur Springs, W. Va., Dec. 7-9. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Western Surgical Association, St. Louis, Dec. 2-4. Dr. Warren H. Cole, 1853 W. Polk St., Chicago 12, Secretary.

GOVERNMENT SERVICES

NAVY

PERSONALS

The Bureau of Medicine and Surgery announces the retirement of Captain Frederick L. McDaniel, director of the professional division of the Bureau of Medicine and Surgery, after more than thirty years' service.

Captain Frank M. Cannon, San Rafael, Calif., of the Medical Reserve Corps has volunteered for recall to active duty and will be assigned to the Naval Dispensary, San Francisco.

Commander Thomas F. Dowd, of Philadelphia, of the Medical Reserve Corps has been recalled to active duty and ordered to postgraduate instruction under the new Navy Graduate Medical Training Program for a residency in obstetrics and gynecology at the Naval Hospital, Philadelphia.

Lieut. Comdr. Frederick B Carlson, Ashtabula, Ohio, on inactive reserve status, has been commissioned in the Medical Corps of the Regular Navy.

Lieutenant Marcus L. Howard, Dawsonville, Texas, has been recalled to active duty at his own request from an inactive status in the Reserve Corps.

Lieutenant (jg) James B. Smith, MCR, New York, has reported to the Naval Hospital, San Diego, Calif., for his first active duty.

Commander F. X. Banvard, MC, Retired, Baltimore, has volunteered for recall to active duty and will be assigned to the Naval Gun Factory, Washington, D. C.

The following Medical Reserve Corps officers have reported for their first active duty for postgraduate instruction under the new Graduate Medical Training Program: Lieutenants (jg) James B. Flanagan, Tyler, Texas, residency in internal medicine at John Gaston Hospital, Memphis, Tenn.; James H. Wells, Springfield, Mo., residence in neuropsychiatry at Indianapolis General Hospital, Indianapolis.

AWARDS AND COMMENDATIONS

Captain Herbert G. Shepler

In a ceremony in the Office of the Surgeon General October 11, Rear Admiral C. A. Swanson, in behalf of the Commander-in-Chief of the United States Pacific Fleet, presented a letter of commendation to Captain Herbert G. Shepler, M.C. The citation read as follows:

For meritorious conduct in the performance of his duties as senior medical officer on the U. S. S. *Hancock* during operations against the enemy from Oct. 10, 1944, to Aug. 15, 1945. His resourcefulness in handling large numbers of casualties resulting from enemy action contributed materially to the ability of his ship to continue offensive operations against the enemy. His leadership and skilful training of his men provided a highly effective medical organization which greatly enhanced the fighting effectiveness of his ship. His performance of duty was outstanding and his conduct was at all times in keeping with the highest traditions of the United States Naval Service.

Dr. Shepler was graduated from Ohio State University College of Medicine and entered the medical corps of the Navy June 25, 1929.

PUBLIC HEALTH SERVICE

FIRST PUBLIC HEALTH ATTACHÉ APPOINTED

Dr. Morris B. Sanders has been appointed as the first Public Health Attaché to represent the United States abroad. Dr. Sanders has been assigned to the embassies at Paris, Brussels and The Hague, with residence in Paris. Among his duties will be the collection of information from those countries on health, medical research, prevalence of diseases of interest to the United States and the extent of health insurance in their programs; familiarizing himself with the administration and technic in the national public health services abroad, and identifying himself with the public health and medical research of the countries to which he is assigned.

Dr. Sanders, a graduate of Harvard Medical School, has since 1932 worked in France, serving on the staff of the American Hospital in Paris, chiefly in the field of anesthesia. He joined the U. S. Public Health Service reserve as medical director May 24, 1948, on which day he was detailed to the State Department. During the war he was anesthetist for the American Hospital, used as a French Auxiliary Hospital, and was a member of the Commission for Oxygen Therapy for the French Armies under Dr. Alexis Carrel. He was held in a German concentration camp from December 1941 until April 1942, and when released returned to work as an anesthetist at the French Red Cross.

NATIONAL INSTITUTE OF DENTAL RESEARCH

Under the authority of an Act of Congress the Federal Security Administrator has announced the establishment of the National Institute of Dental Research, which will conduct a broad attack on dental diseases and related diseases of the mouth. Congress has authorized appropriations of $750,000 a year for this program, which will include research in the Institute's laboratories at Bethesda, Md.; financial grants to outside institutions for research and training of professional personnel and fellowships and traineeships in the Institute to promote training and research in dental diseases. The director of the new Institute will be H. Trendley Dean, D.D.S., who has been Director of the Dental Research Section of the National Institutes of Health of the Public Health Service.

MISCELLANEOUS

TWO NEW ISOTOPES FOR RESEARCH

Limited quantities of two important new research materials—hydrogen-3 and helium-3—have been added to the list of isotopes being distributed by the United States Atomic Energy Commission to scientists and research institutions throughout the United States, it was announced by the Atomic Energy Commission. Hydrogen-3, also called tritium, is a radioactive gas with a half-life of about twelve years. As the only radioisotope of hydrogen, it should prove of special value as a "tracer" in medical, biologic and chemical research. When combined with oxygen, tritium can also be used as the valuable research tool known as heavy heavy-water. Helium-3, a stable isotope, is only one-millionth as abundant in nature as ordinary helium. Now that it is available for laboratory study, it may provide valuable clues to the still largely unknown properties of the helium nucleus. Because of the extreme simplicity of their atomic nuclei, both materials are readily adaptable to investigations in support of basic atomic theory. Already, important knowledge of the fundamental forces which hold the atomic nucleus together has been gained in experiments with tritium and helium-3 by Dr. Herbert Anderson and Dr. Aaron Novick at the Atomic Energy Commission's Argonne National Laboratory, Chicago, where the new isotopes are produced.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Art Exhibit.—The first postwar exhibit of the Los Angeles Physicians' Art Society will be held November 15-30 in the lounge of the Los Angeles County Medical Association. Paintings, sculptures, pottery, photographs and other works of art should be received at the association not later than November 12. The awards will be presented on the evening of November 19.

CONNECTICUT

Society News.—At the recent meeting of the Connecticut Cancer Society at Waterbury, Dr. Creighton Barker, New Haven, executive secretary of the Connecticut State Medical Society, was elected president, and Dr. Alfred L. Burgdorf, Hartford, was made chairman of the medical advisory committee.

Rheumatic Fever and Cardiac Program.—The Rheumatic Fever and Cardiac Program of New Haven begins its second year with an expanded program to combat heart disease. A cardiac registry of 900 New Haven school children to be examined has been compiled by the bureau of nursing of the New Haven Department of Health. These school children are to be examined and referred to private physicians for follow-up or to the clinic facilities. The New Haven Rheumatic Fever and Cardiac Program was established a year ago by the Connecticut State Department of Health, Department of Pediatrics, Yale University School of Medicine, and the City Health Department (The Journal, Oct. 11, 1947, p. 363).

FLORIDA

Personal.—Dr. T. Elam Cato, Miami Beach, director of the Dade County Health Department, was recently elected president of the Florida Public Health Association.

Blood Bank and Research Foundation.—The building housing the Dade County Blood Bank and its Medical Research Foundation was dedicated on Labor Day in Miami. The blood bank is designed to provide for the collection of as much as 400 bottles of blood a day in an emergency. Research in bacteriology, biochemistry, immunology and hematology will be carried out in the new research building. Both the blood bank and the foundation are sponsored by the Dade County Medical Association, and their direction will be under the control of technical committees drawn from its membership.

ILLINOIS

Personal.—Dr. William L. McNamara, Hines, has been appointed full time director of the pathology department of Memorial Hospital, Elmhurst, Ill. Dr. McNamara is assistant professor of pathology at Northwestern University Medical School.

Conference at Rockford.—A graduate Conference for the First Councilor District of the Illinois State Medical Society will be held at the Hotel Faust, Rockford, November 10, 2 p. m., under the auspices of the state society. Chicago physicians participating are:

Henry G. Poncher, Therapy in Infancy and Childhood.
Ralph B. Bettman, Intrathoracic Surgery.
Paul S. Rhoads, Inhalation of Penicillin Dust.
Percy E. Hopkins, Voluntary Prepayment Medical Care.

Dr. Percival Bailey, Chicago, will speak at the dinner on "Japanese B. Encephalitis." The First Councilor District embraces the county medical societies of Boone, Carroll, DeKalb, Jo Daviess, Kane, Lake, McHenry, Ogle, Stephenson and Winnebago.

Chicago

Annual Lectureship.—The Phi Lambda Kappa Fraternity at the University of Illinois College of Medicine has established an annual lectureship. The initial lecture, on "Behavior and Neurosis," was given at the college October 27 by Dr. Jules H. Masserman, assistant professor of nervous and mental diseases at Northwestern University Medical School.

Research on Alcoholism.—The Research Council on Problems of Alcoholism, an associate of the American Association for the Advancement of Science, has granted $4,826 to the Chicago Committee on Alcoholism for the conduct of research work in a Chicago institution. This is the third grant made this year by the council, the others being to Cornell University Medical College, New York, $30,000 underwriting the second year of a five year project, and $20,000 to New York University College of Medicine-Bellevue Hospital.

University Appointments.—Dr. Robert C. Berson of Rye, N. Y., has been appointed assistant dean of the University of Illinois College of Medicine and assistant director of clinics for the university hospitals. Dr. Berson, a graduate of Vanderbilt University School of Medicine, Nashville, 1931, has been an attending physician at the United Hospital, Port Chester, N. Y. He was attached to the 300th General Hospital during the war. Dr. George R. Minor of Charlotesville, Va., has been appointed assistant professor of surgery. A graduate of the University of Virginia Department of Medicine, Charlottesville, 1940, Dr. Minor served as an instructor in surgery at the University of Michigan Medical School, Ann Arbor, from 1947-1948.

Survey of Q Fever.—Representatives of management and labor in the meat and dairy industries met at the health department recently to arrange for the collection of 1,000 blood samples for a survey of Q fever in Chicago. The disease appears to be an occupational hazard to livestock workers. For the survey the Chicago City Health Department teams are collecting blood samples from packing house workers, slaughter house workers, rendering plant workers and workers on dairy farms, at raw milk receiving stations and at pasteurization plants. Q fever was first reported in Australia in 1937. Although no cases diagnosed as Q fever were reported here in 1947 or in 1948 to date, there were 30 cases reported among Chicago packing house workers in 1946.

MASSACHUSETTS

Personal.—Dr. Theodore Fischer-Galati, Lawrence, has been reinstated as professor of ophthalmology at the University of Rome, Italy. He expects to lecture next spring on American Contributions in the Advancement of Ophthalmology before returning to the United States to practice.

Frances Stern Scholarship Fund.—The Frances Stern Scholarship Fund has been established at Tufts College Medical School, Boston, in honor of Miss Frances Stern, an authority in the field of nutrition who died last year. Tufts College, in recognition of the high standards she set, is now granting a master's degree to those who satisfactorily complete a new course of study in nutrition and dietetics in conjunction with the field work completed at the Frances Stern Food Clinic. Contribution to the fund should be sent in care of Boston Dispensary, 25 Bennet Street, Boston.

MINNESOTA

Personal.—On a recent trip to South America Dr. Albert C. Broders, Mayo Clinic, Rochester, was made an honorary member of the Faculty of Biology and Medical Sciences of the University of Chile; he is one of five North Americans to receive this honor.——Dr. Philip S. Hench, Rochester, has left for Europe to deliver the Samuel Hyde Memorial Lecture at the Royal Society of Medicine in London and the Heberden Oration before the Heberden Society in London. He will also address the Norwegian and Danish rheumatism associations and will speak in Norway.

Report of Cancer Detection Center.—The University of Minnesota reports that more than one half of the 957 persons examined at the Cancer Detection Center in Minneapolis during the first seven months of its operation had abnormalities requiring medical attention, including 15 definite cases of cancer, 235 precancerous lesions, 131 benign tumors, 270 nontumorous but abnormal conditions and 40 suspicious tumors. About 4,000 are waiting for appointments at the center. Persons requiring medical attention are referred to their personal physicians for treatment. A registration fee of $5 is charged unless the person is unable to pay. A project of the university's medical school, the Cancer Detention Center is financed in part by the Minnesota state division of the American Cancer Society, the National Cancer Institute of the U. S. Public Health Service and the university's malignant disease research fund.

NEBRASKA

Personals.—A parade was held recently at the Nemaha County Fair to honor Dr. Isaiah W. Irvin, a general practitioner and former mayor of Auburn.——The investiture of Dr. Adolph Sachs, Omaha, as Knight Commander, with Star, of Saint Gregory the Great, conferred by Pope Pius XII, is to be conducted by the Archbishop of Omaha, the Most Reverend Gerald T. Bergan, November 19 at Hotel Fontenelle, Omaha at 7:30 p. m.

Hospital News.—Ground was broken September 13 for a one hundred and thirty-five bed addition to St. Joseph's Hospital, Omaha. The five story addition, to cost about $1,686,460, will be called the Our Lady of Victory unit, and its facilities will be devoted to the care of nervous and mental patients.

NEW JERSEY

Public Health Week.—Under the sponsorship of the Medical Society of New Jersey, its twenty-one component county medical societies, its woman's auxiliary and the local and state health departments, Public Health Week will be celebrated in New Jersey November 8-12. Public speakers, forums, radio talks, newspaper features and motion pictures will make up the program. An effort will be made to interpret the advances in medical science to the people.

NEW YORK

Graduate Assembly in Anesthesiology.—The New York State Society of Anesthesiologists will hold its third graduate assembly at the Hotel New Yorker, New York, December 9-10. Each panel will be devoted to teaching fundamental subjects related to clinical applications. Out of state members of the faculty include Drs. Cecil K. Drinker, Boston; Isidor S. Ravdin, Philadelphia; James C. White, Boston; Maurice H. Seevers, Ann Arbor, Mich.; Archibald R. McIntyre, Omaha, Neb., and John C. Krantz Jr., PH.D., Baltimore.

Graduate Lectures.—The Medical Society of the State of New York and the New York State Department of Health have arranged the following graduate lectures: The Alleghany County Medical Society meeting at the Hotel Belmont in Belmont November 11 at 2 p. m. will hear Dr. Henry C. Shaw, Rochester, speak on "Common Diseases of the Skin." On November 18 Glens Falls Academy of Medicine will hear Dr. Linn J. Boyd, New York, speak on "Pulmonary Embolism" at the Crandall Library, Glens Falls, at 8:30 p. m. Four lectures have been arranged for the Nassau County Medical Society on Thursday afternoons at 4 p. m. at the Nassau Hospital Auditorium, Mineola:

Nov. 11, Herman Goodman, New York, The Prescription for the Skin; General Principles in Prescription.
Nov. 18, Stuart L. Vaughan, Buffalo, Diagnosis and Treatment of the Anemias.
Dec. 2, George E. Anderson, New York, Detection in Diabetes.
Jan. 27, Richard S. Gubner, New York, Newer Concepts and Therapy of Hypertension.

New York City

Diabetes Association Meeting.—The New York Diabetes Association, Inc., will hold an open meeting sponsored by the Committee on Internal Medicine at the New York Academy of Medicine November 12 at 8:30 p. m. Dr. Jerome W. Conn, associate professor of internal medicine at the University of Michigan Medical School, Ann Arbor, will speak on metabolic effects of pituitary adrenocorticotropic hormone. Drs. George E. Anderson, Jacques L. Gabrilove and E. Abbie I. Knowlton of New York will take part in the discussion.

Industrial Health Conference.—The Commerce and Industry Association of New York, Inc., and New York's doctors and businessmen will hold a health conference December 1 in cooperation with the Institute of Industrial Medicine of the New York University-Bellevue Medical Center and medical organizations. Speakers at the meeting, which will be held at the headquarters of the association, 233 Broadway, include Drs. Edward J. Steiglitz, Washington, D. C.; Harry S. Mustard, New York; Royd R. Sayers, Washington, D. C.; John J. Wittmer, New York, and Dean Thorndike Saville, New York. Dr. Anthony J. Lanza of the Institute of Industrial Medicine will serve as chairman.

Lectures for Laymen.—The New York Academy of Medicine will present its fourteenth series of Lectures to the Laity on "The Future in Medicine" beginning November 11 and extending through Feb. 10, 1949, at the academy, 8:30 p. m. Admission to the lectures, which are broadcast by WNYC, is free.

Nov. 17, Mr. Robert P. Patterson, New York, The Linsly R. Williams Memorial Lecture: Some Problems in Law and Medicine.
Dec. 9, Ephraim Shorr, New York, The Endocrines: Masters or Servants?
Dec. 23, Leo Alexander, Boston, The One Hundredth Anniversary Discourse of the New York Academy of Medicine: Science Under Dictatorship.
Jan. 13, William C. Boyd, Ph.D., Boston, Blood and Man.
Jan. 27, John R. Dunning, Ph.D., New York, The Future of Nuclear Energy.
Feb. 10, George E. Gardner, Boston, The George R. Siedenburg Memorial Lecture: The Criminal in Our Midst.

OHIO

Professor Lauda to Lecture.—Ohio State University has invited Dr. Ernst von Lauda, professor of medicine and director of the First Medical Clinic of the University of Vienna, as a visiting professor in medicine beginning about Jan. 8, 1949. The university is arranging a speaking tour for him from January 15 to March 1. The titles of his lectures will be Differential Diagnosis of Various Types of Liver Cirrhosis, Primary Ligurias, Pathogenesis of Tetany, Proctalgia Fugax (rectal neuralgia), Dyspragia Arteriosclerotica Intestinalis Intermittens (abdominal angina), Differential Diagnosis and Therapy of Enteritis and Ulcerative Colitis, Claudicatio Venosa, and Anemia, Type Lederer.

PENNSYLVANIA

Society Election.—At the annual meeting of the Pennsylvania Psychiatric Society in Philadelphia October 7, Dr. Thomas A. Rutherford, Waymart, became president; Dr. Harold L. Mitchell, Pittsburgh, president elect, and Dr. Philip Q. Roche, Philadelphia, secretary-treasurer. The society voted to make formal application to the Council of the American Psychiatric Association for recognition as the district branch society of the association for Delaware and Pennsylvania.

Philadelphia

Personal.—Dr. Edwin J. Fellows, associate professor of pharmacology at Temple University School of Medicine, has been appointed head of the pharmacologic laboratories at Smith, Kline and French Laboratories. Dr. Fellows will retain his professorship at the university, where he has been on the faculty since 1935.

University Appointment.—Dr. Arno E. Town, clinical professor of ophthalmology, New York University College of Medicine, was appointed professor of ophthalmology at the Jefferson Medical College July 1, succeeding Dr. Charles E. Shannon, Philadelphia, who retired on that date. Dr. Town was graduated from Jefferson Medical College in 1926.

Meeting of Resident Physicians.—The annual banquet of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held December 7 at the Penn Sheraton Hotel. The guest of honor will be Dr. Edward J. G. Beardsley, Philadelphia. For reservations address the secretary-treasurer, Dr. Robert C. McElroy, 133 S. 36th St., Philadelphia 4.

Ordinance on Air Pollution Control.—An ordinance establishing a Division of Air Pollution Control in the Bureau of Health of Philadelphia has been approved. The ordinance also establishes within the bureau an Air Pollution Control Board of seven members, who will receive no compensation. The board is to assist hotel, apartment, commercial and industrial building owners in maintaining proper combustion of fuel. Fines and imprisonment are provided for those who violate the provisions of the ordinance.

UTAH

State Medical Election.—Dr. Orin A. Ogilvie, Salt Lake City, was installed as president of the Utah Medical Association at its annual meeting in September. Dr. Conrad H. Jenson, Ogden, was named president elect, and Dr. Leslie B. White of Salt Lake City was relected treasurer. The next annual meeting will be held in Salt Lake City.

Dr. Branch to Head Psychiatry Department.—Dr. C. H. Hardin Branch, until recently executive director of the Institute of Pennsylvania Hospital at Philadelphia, has been appointed professor and head of the newly formed department of psychiatry at the University of Utah College of Medicine, Salt Lake City. Dr. Branch, a graduate of Tulane University of Louisiana School of Medicine, New Orleans, 1935, assumed his duties Oct. 1, 1948.

WISCONSIN

Society News.—At a meeting of the University of Wisconsin Medical Society October 13, Dr. Arthur B. Appleton, professor of anatomy, University of London, discussed "Bronchopulmonary Segments and Variations in Pulmonary Vascular Patterns."

Dr. Joslin to Give Memorial Lecture.—The annual Arthur S. Loevenhart Memorial Lecture will be given by Dr. Elliott P. Joslin of Boston, on "Observations on Diabetes Mellitus," in the auditorium of the Service Memorial Institutes Building, University of Wisconsin Medical School, Madison, November 10 at 8 p. m. Dr. Joslin has long been associated with Harvard University Medical School, where he is an emeritus professor of medicine. He comes to Madison under the sponsorship of the Wisconsin chapter of Phi Delta Epsilon, medical fraternity. Dr. Loevenhart was professor of pharmacology at the state medical school for many years prior to his death, April 19, 1929.

GENERAL

Inter-American Congress on Brucellosis.—The second Inter-American Congress on Brucellosis will be held November 17-20 at Mendoza, Argentina and November 22-26 at Buenos Aires, Argentina under the auspices of the Argentine government and the Pan American Sanitary Bureau. Countries represented on the program are Colombia, Mexico, Peru, Venezuela, Chile, Puerto Rico, Argentina and the United States.

Prof. Baitsell Appointed Editor of Science Magazines.—George A. Baitsell, Ph.D., professor of biology at Yale University, New Haven, has been appointed chairman of the editorial board and editor-in-chief of *Science* and *The Scientific Monthly*. The position of editor of *Science* has been vacant since the death of Willard L. Valentine in 1947. Frank L. Campbell, Sc.D., Washington, D. C., resigned as editor of *The Scientific Monthly* this year.

Death Rate Slightly Increase.—The crude death rate for the United States for 1947 was, according to the National Office of Vital Statistics in the U. S. Public Health Service, 10.1 deaths per 1,000 estimated population. This was the second lowest rate ever recorded for the United States, the lowest rate having been 10.0 in the year 1946. A total of 1,445,370 deaths was registered in the United States during 1947, an increase of 49,753 over the number recorded in 1946.

Gastric Cancer Conference.—A gastric cancer conference, sponsored by the National Cancer Institute, will be held in San Francisco December 13-14, at Stanford University Medical School. The meeting is open to all members of the medical profession and includes among the speakers Drs. John H. Morton, Rochester, N. Y.; George N. Papanicolaou, New York, and Leo G. Rigler, Minneapolis. Information may be obtained from Dr. Morris K. Barrett, Secretary, Gastric Cancer Committee, National Cancer Institute, Bethesda 14, Md.

Diamond Jubilee of Nursing.—The American Nurses' Association of 162,000 registered nurses is sponsoring a Diamond Jubilee during Nurses Progress Week, November 14-20. The memory of Linda Richards, America's first professional nurse, is to be especially honored. Celebrations throughout the country will help focus attention on the improvement of nursing service through the improvement of schools of nursing, economic security for all nurses and adequate licensure laws. It is expected also to aid the recruitment of 40,000 additional students for approved schools of nursing.

Research in Cardiovascular Disease.—The American Heart Association has announced that fellowships for research in cardiovascular disease are available. Application blanks may be obtained from the Medical Director, American Heart Association, 1775 Broadway, New York 19, New York. The aim of the association is to develop a continuing program of research in the field of cardiovascular disease including rheumatic heart disease. Its program will be coordinated with that of the National Heart Institute of the National Institutes of Health, U. S. Public Health Service and the Life Insurance Medical Research Fund.

Incidence of Poliomyelitis.—A total of 1,122 cases of poliomyelitis was reported during the week ended October 20, as compared with 1,207 for the preceding week, a decrease of 85 cases as compared with a decline of 322 cases the preceding week, according to the U. S. Public Health Service. The total to date is 21,515, as compared with 20,686 for the corresponding period of 1946, and for the corresponding week in 1946 a total of 1,042 cases. During the remainder of the year 1946, a total of 4,578 cases was reported. Decreases were reported in most of the states, the principal exceptions being increases in Wisconsin, from 35 to 57, and in California, from 223 to 234, probably as the result of inclusion of delayed reports.

Medical Director of Multiple Sclerosis Society.—Dr. Cornelius H. Traeger, New York, has been appointed medical director of the National Multiple Sclerosis Society. Dr. Traeger, a graduate of Columbia University College of Physicians and Surgeons, New York, is attending physician and co-chief of Arthritis Clinic at the Hospital for Special Surgery and consulting attending physician in internal medicine and chief of the Arthritis Clinic at Roosevelt Hospital. Dr. Traeger will divide his time for the present between his practice and the medical activities of the society, which, since its inception two years ago, has financed seven projects on the cause and treatment of multiple sclerosis. Among these are two multiple sclerosis research clinics, in Boston and in Albany, N. Y. It is planned to finance other projects already approved by the society's Medical Advisory Board when funds are available. Dr. Traeger, as medical director, will administer and coordinate medical research in this field.

Meeting of UNESCO Commission.—In announcing the recent Boston conference of the United States National Commission for the United Nations Educational, Scientific and Cultural Organization, it was stated that more than $150,000,000 in money, materials and equipment was sent abroad in 1946 and 1947 for educational reconstruction in ravaged lands and that thousands of students and teachers, including scores of scientists, have been exchanged with countries all over the world to spread knowledge and international understanding. One hundred teachers were brought to the United States in a single "exchange," and 70 foreign students were provided with technical training through a single institution. The National Commission has sought to stimulate these programs through many national organizations and various types of conferences. The chairman of the National Commission is Milton S. Eisenhower, president of Kansas State College, who gave the opening address at the Boston conference.

Meeting of the Industrial Hygiene Foundation.—Health at Work is to be the subject of the annual meeting of the Industrial Hygiene Foundation of America at Mellon Institute, Pittsburgh, November 18. The program is as follows:

Mr. Andrew Fletcher, New York, chairman of the foundation, and Mr. John F. McMahon, Pittsburgh, managing director, How Big is Our Job?
Thomas Parran, Pittsburgh, Good Health Is Good Business.
John Z. Bowers, Baltimore, Atomic Energy, Industrial Health Implications.
Mr. Theodore F. Hatch, Mr. W. C. L. Hemeon and Dr. C. Richard Walmer, Pittsburgh, What the Foundation is Doing.
William P. Yant, Sc.D., Pittsburgh, Industrial Hygiene Codes and Regulations.
Lillian M. Gilbreth, Sc.D., Montclair, N. J., The Man and the Job.
Mack M. Shafer, Dayton, Ohio, Selection and Placement of People.
Theodore G. Klumpp, New York, Resources of the Older Employee.
Theodore C. Waters, Baltimore, Industrial Health Legislation in 1948.
Mr. Joseph N. Scanlon, Boston, Health and Safety as Causes of Industrial Peace.

Sugar Research Foundation Award.—Entries for the Sugar Research Foundation's 1949 Fourth Intermediate Prize Award of $5,000 should be submitted to the executive secretary of the National Science Fund of the National Academy of Sciences on or before Jan. 1, 1949. The award will be given in recognition of discoveries, inventions or developments in the chemistry, physiology, metabolism or technologic application of carbohydrates which contribute most significantly to an understanding of the functions of sugar (sucrose) or to the practical utilization of sugar (sucrose) as a food or in medicine, agriculture, the arts, the industries or other fields of human endeavor. Selection will be announced about March 15, 1949. Winners of the Intermediate Annual Awards are eligible for the Grand Prize of $25,000 to be given March 1, 1950 for the most important work during the five years preceding. For further details address the Executive Secretary, National Science Fund of the National Academy of Sciences, 2101 Constitution Ave., N.W., Washington 25, D. C.

LATIN AMERICA

Mexican Medical Congress.—The Third Mexican Medical Congress will be held at Hospital General, Mexico City, November 7-13, under the presidency of Dr. Abraham A. González, Mexico City. There will be plenary sessions on gastroduodenal ulcer, nutrition, gastritis, cancer, liver and nutrition, diarrheas, proteins and amino acids. Among the guests will be Drs. John H. Garlock and Arthus H. Blakemore of New York, Henry L. Bockus of Philadelphia, Robert Elman of St. Louis, Sidney A. Portis of Chicago, Fernando Milanés of Havana, Cuba, and Pablo Luis Mirizzi of Córdoba, Argentina. Social activities have also been planned.

Marriages

Frank Windholz, San Francisco, to Mrs. Grace Patricia Salter of New York and Los Angeles, July 19.

Daniel W. Coughlan, Des Moines, to Miss Jacqueline Jeanne DePuy of Centerville, Iowa, July 25.

George W. Groth Jr., Sierra Madre, Calif., to Miss Eileen Margaret Ferguson of Monrovia, July 10.

Charles W. Maplethorpe Jr., Toledo, Ohio, to Miss Dorothy Bowen of Muscatine, Iowa, July 25.

Hartwig Moss Adler, New Orleans, to Miss Loretta Albert at Galveston, Texas, July 16.

Chester J. Fortuna to Miss Marie Mildred Lorentz, both of Rochester, N. Y., July 3.

Elbert Hubbard III to Miss Rita Marie Fath, both of Buffalo, N. Y., July 3.

Deaths

George Linius Streeter, Baltimore; born in Johnstown, N. Y., Jan. 12, 1873; Columbia University College of Physicians and Surgeons, New York, 1899; demonstrator in anatomy of the nervous system at Albany Medical College, 1901-1902; served as instructor in anatomy at Johns Hopkins University School of Medicine, Baltimore, and from 1906-1907 as assistant professor of anatomy at the Wistar Institute of Anatomy and Biology, University of Pennsylvania, Philadelphia; professor of anatomy and director of the anatomy laboratory, University of Michigan Medical School, Ann Arbor, from 1907 to 1914, when he went to the Carnegie Institution of Washington as research associate, holding that position until 1918; director of the department of embryology at the institution from 1918 to 1940 and chairman of the division of animal biology from 1935 to 1940, when he became research associate; to mark his many years of service to the institution, volume 30 of the Contributions to Embryology, which appeared Dec. 31, 1942, was dedicated to him; the tribute also recognized his work in serving as editor of the volumes 8 to 29 during the period 1917 to 1940; formerly associate editor of the *American Journal of Anatomy;* a member of many national scientific societies, in 1926 he was president of the American Association of Anatomists; received the doctor of science degree from Trinity College in Dublin in 1928 and Union College in New York in 1930; in 1935 was awarded the doctor of laws degree from the University of Michigan; his research had been concerned with human embryology and development of the central nervous system, the internal ear and experimental biology; trustee of the Samuel Reading School; died in the Nathan Littauer Hospital, Gloversville, July 27, aged 75, of coronary thrombosis.

Albert August Gartner ⊕ Buffalo; born in Buffalo July 10, 1887; University of Buffalo School of Medicine, 1914; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; member of the House of Delegates of the American Medical Association from 1943 to 1948; chairman of the board of trustees of the Medical Society of the State of New York; served overseas during World War I; assistant professor of orthopedic surgery at his alma mater; affiliated with the Edward J. Meyer Memorial Hospital, Millard Fillmore Hospital and the Sisters of Charity Hospital in Buffalo; on the consulting staffs of the DeGraff Memorial Hospital, North Tonawanda, J. N. Adam Memorial Hospital, Perrysburg, Jones Memorial Hospital, Wellsville, and Our Lady of Victory Hospital in Lackawanna; died September 9, aged 61, of carcinoma of the esophagus.

George Bolling Lee ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1896; served as professor of gynecology and obstetrics at New York Polyclinic Medical School and Hospital; veteran of the Spanish-American War and World War I; fellow of the American College of Surgeons; for many years on the staffs of Bellevue Hospital, Woman's Hospital and the Hospital for Joint Diseases; member of the board of trustees of the Washington and Lee University in Lexington, Va., died in St. Luke's Hospital, July 13, aged 75, of fracture of the hip received in a fall.

Herbert Benjamin Allen ⊕ Austin, Minn.; University of Minnesota Medical School, Minneapolis, 1937; medical director of the George A. Hormel and Company; died in Bel Air, Calif., August 24, aged 42, of coronary heart disease.

James Samuel Alsobrook, Rossville, Ga.; Atlanta College of Physicians and Surgeons, 1899; member of the American Medical Association; past president of the Walker County Medical Association; at one time a member of the state senate; served as mayor and postmaster; died August 4, aged 77, of carcinoma of the prostate.

William Marsh Anderson ⊕ Haddonfield, N. J.; Boston University School of Medicine, 1906; served on the staff of the Cooper Hospital, Camden, where he died July 25, aged 67, of coronary occlusion.

Ernest Joseph Anthony, Black Mountain, N. C.; State University of Iowa College of Medicine, Iowa City, 1909; member of the American Medical Association and the Iowa State Medical Society; affiliated with Mission and St. Joseph's hospitals in Asheville; died August 27, aged 65, of cerebral hemorrhage.

Arthur Max Aszmann ⊕ East St. Louis, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1910; past president of St. Clair County Medical Society; died August 4, aged 62, of coronary occlusion.

David G. Bardwell ⊕ Charleston, Miss.; Memphis (Tenn.) Hospital Medical College, 1904; died August 10, aged 70, of heart disease.

Sidney Conroy Barrow ⊕ Shreveport, La.; Memphis (Tenn.) Hospital Medical College, 1901; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society and Radiological Society of North America; fellow of the American College of Radiology; past president of the Shreveport Medical Society and the Louisiana State Medical Society; formerly editor of the *Tri-State Medical Journal* (Arkansas, Louisiana and Texas); died August 11, aged 72, of uremia.

Joseph Mitchell Barsky ⊕ Wilmington, Del.; Jefferson Medical College of Philadelphia, 1914; retired as a brigadier general of the Delaware National Guard after twenty-five years' service; awarded the Legion of Merit in 1944 for outstanding service as a sanitary inspector at an island base in the Pacific from February 1942 to February 1943; served during World War I; past president of the New Castle County Medical Society; affiliated with the Wilmington General Hospital, where he died July 31, aged 56, of coronary thrombosis.

Carroll Charles Beach, Hartford, Conn.; Boston University School of Medicine, 1899; formerly served with the Connecticut Naval Militia; died August 16, aged 73, of arteriosclerotic heart disease.

Joseph Bear ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1912; assistant professor of obstetrics at his alma mater; member of the South Atlantic Association of Obstetricians and Gynecologists; president of the Richmond Obstetrical and Gynecological Club; served during World War I; affiliated with the Retreat for the Sick, St. Luke's Hospital, Medical College of Virginia Hospital, Grace Hospital, St. Elizabeth's Hospital and the City Home; died August 28, aged 59, of coronary thrombosis.

William Frederick Bender ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1913; served on the gymnasium staff of Columbia University and with the urologic clinic of the outpatient department of St. Luke's Hospital; died August 29, aged 72, of an infection with virus x.

Alice McL. Ross Bennett, Buffalo; University of Buffalo School of Medicine, 1890; died August 9, aged 81, of cerebral thrombosis.

Montgomery Herman Biggs ⊕ Rutherfordton, N. C.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the Southeastern Surgical Association; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; affiliated with Rutherford Hospital, where he died August 28, aged 78, of hemiplegia of the left side and thrombus of the middle meningeal artery.

Benjamin Stephen Black, Rochester, N. Y.; Rush Medical College, Chicago, 1936; member of the American Medical Association; formerly secretary of the Clarke County (Ala.) Medical Society and health officer for Clarke County; served overseas during World War II; formerly affiliated with Mount Morris (N. Y.) Tuberculosis Hospital; died in Strong Memorial Hospital August 30, aged 45, of coronary occlusion.

Leo Blass, Los Angeles; St. Louis College of Physicians and Surgeons, 1908; died in Tel Aviv, Israel, August 21, aged 65, of heart disease.

Courtland Linden Booth ⊕ Portland, Ore.; Western Reserve University Medical Department, Cleveland, 1908; member of the Portland Academy of Medicine; formerly on the faculty at the University of Oregon Medical School; served as secretary of the Oregon State Medical Society; recent chairman of the state and the county committees on industrial health; on the staffs of the Providence Hospital, St. Vincent's Hospital and the Portland Sanitarium and Hospital, where he died July 13, aged 71, of coronary occlusion.

Robert Emmett Bowman, Bronwood, Ga.; Atlanta College of Physicians and Surgeons, 1904; formerly mayor and member of the school board; served during World War I; died in Dawson, July 14, aged 65, of coronary thrombosis.

Theron Robert Bradley ⊕ South Norwalk, Conn.; University of Maryland School of Medicine, Baltimore, 1914; died July 7, aged 69, of coronary thrombosis.

Erwin Sheridan Briggs, Warren, Pa.; Jefferson Medical College of Philadelphia, 1906; past president and secretary of the Warren County Medical Society; member of the American Medical Association; served during World War I; secretary of the board of health of Warren and school district physician; county medical director; affiliated with Warren General Hospital, where he died August 18, aged 71, of cerebral thrombosis.

Stanley Needham Brinson, Memphis, Tenn.; Memphis Hospital Medical College, 1908; member of the American Medical Association; served overseas during World War I; died August 1, aged 67, of heart disease.

George W. Brooks, Tustin, Mich.; Detroit College of Medicine, 1901; died July 22, aged 69, of cirrhosis of the liver and chronic nephritis.

Carl Wilson Brown, Lancaster, Ohio; Starling-Ohio Medical College, Columbus, 1910; member of the American Medical Association; secretary of the Fairfield County Medical Society; served overseas during World War I; a medical examiner for the Selective Service Board during World War II; for many years affiliated with the Boys' Industrial School Hospital; on the staff of the Lancaster Municipal Hospital, where he died August 12, aged 60, of cerebral hemorrhage.

Everett Rhea Brown, Chicago; Bennett Medical College, Chicago, 1916; died August 20, aged 57, of chronic myocarditis and hypertension.

Sidney Pope Brown, Potsdam, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; member of the American Medical Association; served during World War I; for many years county coroner and town and village health officer; served as president and member of the staff of Potsdam Hospital, where he died August 3, aged 78, of diabetes mellitus.

Oliver C. Brunk ⊕ Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1903; served in France during World War I; surgeon for the police department; member of the staff of the Johnston-Willis Hospital; formerly superintendent of the Eastern State Hospital, Williamsburg; died in the Johns Hopkins Hospital, Baltimore, August 19, aged 69, of empyema.

Rosabell A. Butterfield, Indianola, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1907; member of the American Medical Association; served as president of the Warren County Medical Society; died in the Mercy Hospital, Des Moines, July 14, aged 83, of a fracture of the hip received in a fall and uremia.

Michael Howard Gilbert Carmody, Painesville, Ohio; Cleveland Medical College, Homeopathic, 1897; affiliated with the Lake County Memorial Hospital; died August 27, aged 71, of cerebral thrombosis.

Henry Gerald Carroll ⊕ Salem, Mass.; Dartmouth Medical School, Hanover, N. H., 1907; member of the New England Ophthalmological Society; fellow of the American College of Surgeons; affiliated with the Salem (Mass.) Hospital and the Beverly (Mass.) Hospital, where he died August 11, aged 64, of toxemia and agranulocytosis.

Maurice Caspe, New York; University of the City of New York Medical Department, New York, 1886; formerly on the staff of Flower Hospital; died August 31, aged 90, of pneumonia.

Francis Milton Chapman, Milwaukee; Rush Medical College, Chicago, 1892; died in Milwaukee Hospital August 14, aged 78, of injuries received in a fall and diabetes mellitus.

John Albert Chenoweth, Joplin, Mo.; Rush Medical College, Chicago, 1914; member of the American Medical Association; past president of the Jasper County Medical Society; served during World War I and later in the army of occupation; for many years city physician and member of the library board; affiliated with St. John's Hospital and Freeman Hospital; died July 15, aged 58, of coronary occlusion.

Max Climan ⊕ West Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1915; specialist certified by the American Board of Radiology; member of the New England Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; consulting roentgenologist at the Veterans Administration Hospital in Newington; on the staff of Mount Sinai Hospital in Hartford, where he died August 18, aged 56, of pulmonary embolus and bleeding peptic ulcer.

Robert Joseph Conlon ⊕ Washington, D. C.; Georgetown University School of Medicine, Washington, 1918; clinical professor of medicine at his alma mater; for many years chief of staff of Providence Hospital; died August 22, aged 55, of coronary thrombosis.

Marcellus Ellsworth Coy ⊕ Dayton, Ohio; Detroit College of Medicine, 1901; died in Miami Valley Hospital August 1, aged 73, of carcinoma of the bladder.

Alva Brown Craddock ⊕ Asheville, N. C.; Johns Hopkins University School of Medicine, Baltimore, 1918; member of the American College of Chest Physicians; fellow of the American College of Physicians; affiliated with the Asheville Mission and Biltmore hospitals; died July 29, aged 59, of chronic duodenojejunitis.

Alfred Penn Crain ⊕ Shreveport, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1907; city physician; fellow of the American College of Surgeons; past president of the Shreveport Medical Society; affiliated with the North Louisiana, Highland and T. E. Schumpert Memorial sanitariums and Tri-State Hospital; died August 16, aged 67, of coronary occlusion.

Robert James Danehy, Newton, N. C.; St. Louis University School of Medicine, 1943; member of the American Medical Association; died in August, aged 31, of injuries received in a plane crash.

Ludwig Frank Derfus ⊕ Salem, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1911; served overseas during World War I; on the staff of the Salem City Hospital, died August 4, aged 62, of injuries received when struck by a taxicab.

Herman Russell Dewey ⊕ Bellevue, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; served during World War I; died July 30, aged 80, of cerebral hemorrhage.

Frank P. Donahue, Milwaukee; Wisconsin College of Physicians and Surgeons, Milwaukee, 1905; died in St. Camillus Hospital, Wauwatosa, August 18, aged 66, of an accidental fall, myocarditis and essential hypertension.

Samuel Earl Eagon, Cincinnati; Eclectic Medical College, Cincinnati, 1915; served during World War I; died in the Bethesda Hospital August 7, aged 57, of pulmonary embolism and myocardial infarction.

Kurt Eichwald, Zanesville, Ohio; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1920; member of the American Medical Association; died August 31, aged 57.

Erich Richard Erlanger, Rockford, Ill.; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1928; member of the American Medical Association; affiliated with St. Anthony Hospital, where he died August 9, aged 46, of carcinoma.

George B. Fadeley, Arlington, Va.; University of Maryland School of Medicine, Baltimore, 1889; for many years president of the Falls Church (Va.) Bank; died August 18, aged 86.

Charles Hardy Fair, Greenville, S. C.; George Washington University School of Medicine, Washington, D. C., 1909; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; served during World War II; affiliated with Greenville City and St. Francis hospitals; died August 5, aged 67, of chronic pulmonary fibrosis.

Carl Lowell Fairbank, San Diego; Chicago Homeopathic Medical College, 1894; died August 10, aged 76, of arteriosclerosis and pyelonephritis.

George Washington Fithian ⊕ Perth Amboy, N. J.; University of Pennsylvania Department of Medicine, Philadelphia 1899; past president of the Middlesex County Medical Association; served during World War I; formerly city physician; on the staff of Perth Amboy General Hospital, where he died August 9, aged 72, of perforated duodenal ulcer.

Joseph Daniel Foley, Springfield, Mass.; University of Maryland School of Medicine, Baltimore, 1916; served during World War I; assistant city physician; on the courtesy staff of Mercy Hospital, where he died August 13, aged 55, of cerebral hemorrhage.

Edward Aloysius Gorman, Alexandria, Va.; Georgetown University School of Medicine, Washington, D. C., 1898; member of the American Medical Association; for many years health officer of Alexandria; chief medical examiner of the draft boards in Alexandria and Arlington during World War I; on the staffs of Emergency, Sibley and Casualty hospitals in Washington, D. C.; died in Ellicott City, Md., July 19, aged 75, of prostatic carcinoma.

Edward John Grainger, Winthrop, Mass.; Harvard Medical School, Boston, 1903; member of the American Medical Association; died in Concord, N. H., July 25, aged 70, of gastric hemorrhage.

Edgar Agassiz Green, Ridgway, Ill.; Barnes Medical College, St. Louis, 1898; died July 26, aged 74, of myocarditis and hypertension.

Bruce Garfield Hamlin, Scranton, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1909; member of the American Medical Association; on the staff of Hahnemann Hospital; died July 30, aged 67, of coronary thrombosis.

John La Fayette Hart, Lancaster, Ky.; Hospital College of Medicine, Louisville, 1905; member of the American Medical Association; died in the Ephraim McDowell Memorial Hospital, Danville, July 23, aged 70, of injuries received in an automobile accident.

Alvin Thomas Jordan, Hurricane, W. Va.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; died in Charleston July 20, aged 72, of carcinoma of the stomach.

Clarence W. Keene ✠ Silverton, Ore.; University of Oregon Medical School, Portland, 1901; on the staff of Multnomah County Hospital; died July 25, aged 73, of heart disease.

Oza Joseph LaBarge ✠ Alexandria, La.; University of Michigan Medical School, Ann Arbor, 1923; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the Utah State Medical Association; served during world wars I and II; chief of the medical division of the Veterans Administration Hospital; died July 28, aged 50, of cerebral hemorrhage.

Norman Jacob Lebhar, New York; Columbia University College of Physicians and Surgeons, New York, 1900; died in the Lenox Hill Hospital July 25, aged 69, of carcinoma of the cecum.

Edmond Rushin Lett, Tallassee, Ala.; Louisville (Ky.) Medical College, 1905; member of the American Medical Association; served during World War I; senior surgeon for the Tallassee Falls Manufacturing Company for many years; died July 18, aged 66, of acute cholecystitis.

Louis Levy ✠ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1908; affiliated with Hotel Dieu and the Touro Infirmary; died July 24, aged 62, of coronary thrombosis.

Luther Longino, Minden, La.; Missouri Medical College, St. Louis, 1882; died July 29, aged 100, of senility.

John Harrison Lynn, Pocatello, Idaho; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1912; for many years city physician; died July 30, aged 72, of coronary thrombosis.

Emanuel Manko, Kansas City, Mo.; University Medical College of Kansas City, 1905; at one time professor of chemistry at the Kansas City College of Pharmacy; for many years on the staff of St. Joseph Hospital; died July 19, aged 74, of arteriosclerosis and pernicious anemia.

Henry James Schwensen ✠ Canton, Ohio; Ohio State University College of Medicine, Columbus, 1925; affiliated with the Aultman Hospital; died July 25, aged 54, of coronary occlusion.

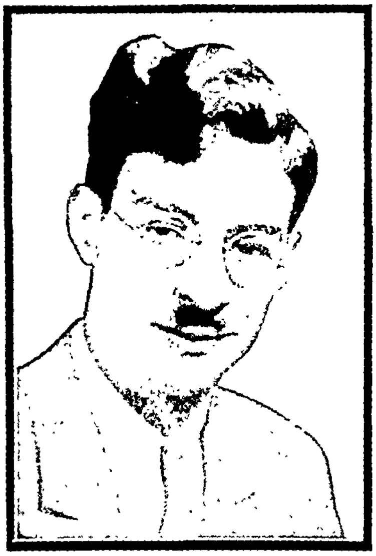
Frank Leslie Snyder, Fort Lauderdale, Fla.; Ohio State University College of Medicine, Columbus, 1935; member of the American Medical Association; fellow of the American College of Surgeons; served during World War II; on the staff of Broward General Hospital; died in West Palm Beach July 28, aged 38, of injuries received in an automobile accident.

William Earl Thompson, Greeley, Colo.; Colorado School of Medicine, Boulder, 1903; member of the American Medical Association, past president of the Weld County Medical Society; on the staff of the Weld County Hospital, where he died July 28, aged 71, of cholecystitis.

Arnold Traubitz ✠ Leadwood, Mo. (licensed in Missouri in 1905); served during World War I; died July 17, aged 68.

Eric R. Twachtman, Cincinnati; Ohio-Miami Medical College of the University of Cincinnati, 1910; member of the American Medical Association; served in France during World War I; on the staffs of the Deaconess and Good Samaritan hospitals; died in Monhegan Island, Me., July 11, aged 62, of coronary occlusion.

Lieut. James F. Handley Jr.
(MC) U.S.N., 1911-1945



Major Louis W. Schneider
M.C., A.U.S., 1912-1944

Lieut. Daniel A. Shapiro
M.C., A.U.S., 1915-1944

KILLED IN ACTION

James Franklin Handley Jr. ✠ Passed Assistant Surgeon, Lieutenant, U. S. Navy, Marshall, Mo.; University of Pennsylvania School of Medicine, Philadelphia, 1937; interned at St. Luke's Hospital in Spokane, Wash., and the U. S. Marine Hospital in Chelsea, Mass.; entered the U. S. Navy in August 1939; missing in action on March 1, 1942 south of Java while serving on the U. S. S. *Langley*; aged 34; presumptive date of death according to the U. S. Navy, Dec. 15, 1945.

Louis W. Schneider, St. Louis; St. Louis University School of Medicine, 1936; member of the American Medical Association; interned at the Jewish Hospital; began active duty in the medical reserve corps of the U. S. Army as a captain in August 1940; later promoted to major in the medical corps, Army of the United States; killed in the South China sea Oct. 24, 1944, aged 32, when a Japanese ship on which he was being transported while a prisoner of war was sunk.

Daniel Albert Shapiro, San Francisco; University of California Medical School, San Francisco, 1940; served an internship and residency at the Mount Zion Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, in July 1941; served on Bataan and was captured by the Japanese on Corregidor; subsequently interned; died in the Asiatic area Oct. 24, 1944, aged 29, when the ship on which he was being transported to Japan was sunk.

A Hostel of New Design for Paraplegics

Much attention has been given since the war to the rehabilitation of the disabled, not only of those whose disability was due to war but also of those disabled in civil life. The latest new departure is the building by the Ministry of Pensions at Osterley, near London, of a hostel for paraplegics. It is situated just off the Great West Road because of the light industries which have been set up there in bright modern factories. In the closing months of the war the pioneer work of the Ministry of Pensions hospital at Stoke Mandeville in the treatment of war paraplegics was described in an article in the *Times*. It was there recorded that paraplegics whose plight had once been regarded as hopeless could be assisted with much success to conquer their disability and that some were working part time in a local wireless factory. The progress made was summed up in the House of Commons by Secretary of the Ministry last June, when he said that of about 600 men and women paraplegics from the war 200 were still in hospital; of the remainder 70 per cent were in full and regular employment.

For the paraplegics at Osterley the cooperation of the firms in the district has been obtained through the Ministry of Labor, so that they will be able to take regular jobs at the factories while living in conditions suited to their special needs and under medical care. Later it may be possible to add bungalows which they can share with their families. The hostel at Osterley has been designed and planned by the Ministry of Works in conjunction with Dr. J. F. E. Prideaux, Director-General of Medical Services at the Ministry of Pensions, in the light of the experience gained at Stoke Mandeville. The staff of the Ministry is taking the greatest interest in finding solutions for many unfamiliar problems which arise. Nothing like this hostel has ever been seen before. Except for the quarters of the male nursing staff over the administrative block, the hostel is all on one floor. Doors and windows are wide to permit the passage of hand-propelled chairs in which the disabled spend all their waking hours indoors. The doors move sideways on ball bearings. The touch of one finger is enough to shut or open them. All the furniture is designed to be just the right height for men in wheeled chairs. They use the cords and pulleys to lift themselves in or out of bed or the bath. There are motor-propelled chairs to take each man to his work at the factory.

Medical Schools in Germany

On the invitation of the American authorities, representatives of the General Medical Council, the Royal College of Physicians and the Royal College of Surgeons visited the American zone of Germany and interviewed both members of the United States Medical Service and German teachers and practitioners, in order to assist the Government of the American zone by informing them and the Germans of the system of medical education in England, the discipline of the medical profession and the new National Health Service. They visited Frankfurt, Heidelberg, Stuttgart, Munich, Erlangen and Wurzburg and had discussions with the deans and professors of the medical faculties and also with representatives of general practitioners. A striking feature of the German situation was the immense number of persons who desire to take up a medical career. At Heidelberg there were 1,600 applicants for one hundred and fifty vacancies. At Munich there were 3,000 medical students. In spite of decisions for their reduction, the number itself forms a serious problem for the university. The difficulty is increased by the serious depletion of the teaching staffs, the destruction of hospital buildings and laboratories and the lack of funds. In order to obtain clinical experience many doctors have taken up posts as unpaid assistants at the hospitals. In Frankfurt, for example, Professor Volhard has 16 paid and 51 unpaid assistants in his large medical clinic. The unpaid assistants live a precarious life, subsisting on the charity of their relations or friends, often with insufficient food. The plight of the students is even worse, for housing accommodation is totally inadequate and books almost unobtainable.

The needs of the medical faculties are both financial and academic. More money is required for the rebuilding of hospitals and laboratories, for the payment of more assistants and especially for the payment of research students. At present little or no research is done because of lack of funds. The serious shortage of German textbooks is unavoidable, but the medical schools are also starved of foreign journals, which they cannot buy because of lack of dollars and sterling. This visit was to the American zone only, but it was ascertained that the same conditions prevail in all the medical schools of Germany. The representatives end with a plea for assistance to Germany "if only as an acknowledgment of what we owe to German medicine in the past."

ITALY

(From Our Regular Correspondent)

FLORENCE, Sept. 15, 1948.

Medical Meetings

The Italian committee for the study on rheumatism and the Italian group for the study on metabolism held their annual meetings in the city of warm springs, Acqui, under the chairmanship of Professor L. Zoia.

Professor Condorelli of Catania reported on "acute rheumatic and subacute atypical episodes." He considered the less common aspects, i. e., those in which rheumatic disease may take its course in the absence of any manifestations in the joints. With no reliable laboratory tests the diagnostic presumption in these cases depends nearly altogether on clinical and therapeutic criteria. From time to time, value will be attributed to small signs, which may acquire a decisive significance for the diagnosis of rheumatic infections. It is important to take into account the remote history to detect rheumatic episodes or occasional mild rheumatic recurrences. In the course of the actual attack, pathologic signs may be presented by the cardiovascular apparatus; for example, unprogressive accentuation of the cardiac sounds, appearance of arrhythmia, electrocardiographic changes. Treatment with large doses of sodium salicylate rather than aminopyrine, which according to the speaker may be considered of great importance for the successful treatment of acute rheumatism, may often prove the rheumatic causation of a condition of the type described.

Professor Condorelli considered two atypical aspects of rheumatic infection without rheumatism: One is characterized by fever of various type and degree in the absence of any objective focal sign, and the other presents precocious visceral localizations of great variety

The report of Professor Bassi dealt with "Lactoflavinic Dysgenovitaminosis."

Mycotic and Leukemic Erythroderma

At a meeting of the Italian Society for Dermatology and Syphilography, Professor Mezzadra of the Clinic of Padova, reported on the relation between mycotic and leukemic erythroderma. Then Professor Mezzadra discussed 3 clinical cases.

The first patient, a woman aged 35, had mycosis fungoides of diffuse polymorphous character with erythroderma. The second patient had mycosis fungoides of premycotic type, but with definite signs of incipient polymorphism. The third case was of a lymphadenic type of erythroderma in a man aged 70.

Microscopic examination of the cutaneous lesions and of those of the lymph nodes of the first patient revealed a typically granulomatous structure with incipient sclerosis and giant cells of Sternberg's type, which recalled the structure of malignant lymphogranuloma. The dominant microscopic characteristic of the case was a cellular polymorphism with the presence of plasma cells, lymphoid cells and fibroblasts, which recalled the structure of infectious granuloma.

These and other structural peculiarities observed were interpreted by the author as an attempt of defense of the organism most characteristic of the pretumorous stage in which the cellular proliferation remains disorderly and is ultimately useless.

From a study of the literature on erythrodermatous mycosis, Professor Mezzadra reached the following conclusions: 1. The term mycotic erythroderma does not always satisfy the classic concept of generalized erythema which persists from the beginning to the end. 2. Some cases described by the term mycotic erythroderma may be disputable because they often may be identified with a diffuse erythrodermic picture, with constant polyadenopathy, hepatosplenomegaly and leukemoid state. 3. There are cases of mycosis fungoides for which the term diffuse mycosis fungoides or mycosis fungoides with erythrodermic state may be more appropriate, so far as the generalization of the cutaneous picture is associated with the juxtaposition of polymorphous lesions. 4. Clinically and microscopically, the lymphadenous erythroderma must be differentiated from the mycotic syndrome, although one must recognize that histogenetically both pictures may be led back to a reticuloendothelial proliferative alteration. 5. Some cases described with the term Hebra's pityriasis rubra may be considered as of lymphadenic erythroderma.

Opaque Transbuccal Clysma of Small Intestine

Professor A. Lura reported at the Medico-Surgical Association of Bologna that for about one year he has been studying at the Radiologic Institute and at the Medical Clinic of the University the administration of the contrast medium for the roentgen diagnosis of the small intestine by means of a catheter introduced into the duodenum. The method for which the term "opaque transbuccal clysma of small intestine" has been coined offers great advantages as compared to the normal administration of the opaque paste, which may be summarized as follows: (1) the possibility of obtaining within a few minutes sight of the entire small intestine and occasionally part of the large intestine; (2) the possibility of following the top of the opaque column in its entire course without too long an exposure to the roentgen rays; (3) study of the small intestine when filled; (4) a study of function of the small intestine under mechanical stimulation—a function test.

In addition the following results may be obtained in practice: determination of the importance of the anatomic lesions of the small intestine, and particularly of neoplastic infiltration, superior to that obtained by normal administration of the opaque paste, particularly with regard to the evaluation of the extent of the involvement of the intestinal tract; study of the small intestine in patients in whom the administration of the contrast medium may be difficult by the normal route because of obstinate vomiting; the possibility of confirming by an examination of short duration whether a palpable mass in the abdomen is intrinsic or extrinsic to the alimentary canal; the possibility of demonstrating or excluding the presence of suboccludent stenosis in cases with doubtful interpretation, and direct demonstration of vicious circle in gastroenteroanastomosis.

DENMARK

(From Our Regular Correspondent)

Oct. 9, 1948.

Professor Schmiegelow's Reminiscences

At the age of 90, Professor Schmiegelow has published an autobiography which brings the reader in touch with more than half a century of the modern history of medicine. This nonogenarian with most remarkable mental and physical vitality was an ailing child and a consumptive young man. In childhood he suffered from scrofula and tuberculous glands, and at the age of 21 contracted severe pulmonary tuberculosis, which flared up again at the age of 30. He has filled the subsequent sixty years of his life with tireless energy. Pen portraits of Koch, Pasteur and Lister are drawn by this Danish surgeon, and a dramatic account is given of a debate at the Fourth International Hygiene Congress in Geneva, where Pasteur abused Koch and Koch abused Pasteur to the great amusement of the audience. The account given of Lister's antiseptic activities is more vivid than flattering.

In 1883, Professor Schmiegelow succeeded in introducing otolaryngology as an independent speciality in hospital practice in Copenhagen, but it took him forty-six years to get this speciality on an equal footing with other disciplines, and it was not till some time after he retired at the age of 70 that the salary of his successor was brought up to that of other University professors. For years his surgical colleagues, Professor Block and Professor Rovsing, sneered at otology as a specialty and at otologists claiming to undertake radical operations in their own field. It must have been with an ironic smile that Professor Schmiegelow consented to operate on Professor Rovsing for cancer of the larynx. Professor Schmiegelow has been a familiar figure at so many international medical conferences and over so long a period that the many who have met this richly endowed, cosmopolitan Dane will revive pleasant memories when they scan his entertaining, running commentary on his own experiences and on the many distinguished men whom he has met.

The High Death Rate Among Danish Doctors

A recent analysis of the causes of death among Danish doctors, published by Marie Lindhardt in the journal of the Danish Medical Association, covers the ten year period 1935 to 1944, during which there were 504 deaths among male doctors. Women doctors are not dealt with in this analysis. Had the death rate been the "normal" for the whole population, there would have been only 437.9 deaths among doctors in the same period. A table in which the main causes of death are classified separately shows that infectious diseases (not including tuberculosis), heart disease and suicides were largely responsible for the excess death rate. The figures which follow in brackets refer to the expected or "normal" death rate.

There were 23 (13.3) deaths from infectious diseases other than tuberculosis, 21 (12.5) deaths from suicide and 128 (81.9) deaths from heart disease. These figures tally well with those of other civilized countries, and they are fairly easy to explain. Doctors succumb often to the infectious diseases because they come more in contact with them than other men. They die of heart disease because their work entails exceptionally heavy strain, but why do Danish doctors, like their colleagues in England, commit suicide so often? It can surely not be a coincidence that all the 21 suicides were carried out by poisons to which doctors have, of course, exceptionally easy access. Here in Denmark, as well as in certain other civilized countries, suicides are more common among the well to do, so-called educated classes than among the lower classes. It is not easy to explain this difference. It might be asked why tuberculosis had claimed only 13 (16.4) deaths among male doctors in the ten year period under review. Is it that this disease is recognized earlier in doctors than in other men? Or does tuberculosis weed out several young men before they have had time to qualify as doctors?

The Late Professor Carl Sonne

The news of Carl Sonne's death last June must have made many scientists in different parts of the world wonder whether this was really the man whose name has already figured in textbooks on bacteriology in connection with dysentery bacilli. He is, in fact, the Sonne of dysentery fame, and his M.D. thesis was based on his now historic study of the various bacilli responsible for dysentery. But this particular study was only a fraction of his scientific output. He was born on the island of Bornholm in 1882, and it was to his home on this island that he retired shortly before his death. As a young man he came under the influence of his countryman, Professor Christian Gram, at the Rigshospital in Copenhagen. His bacteriologic bent led to his appointment as head of the Finsen Institute Laboratory, where one of the most important of his studies concerned the part played by light in the formation of vitamin D in the skin. He sought to ascertain which are the components of the spectrum which have a biologic action on living tissues, and if he did not find all he sought he at any rate made observations which will assuredly be helpful to his successors in this field.

After ten years as head of the Finsen Institute Laboratory, Sonne was put in charge of the Medical Polyclinic of the Rigshospital, and some time later succeeded Lundsgaard as head of Department A, in which as a young man he had studied medicine from the clinical side. But he remained a research worker at the same time, and he and his associates spent many years on the study of the mixture of gases in the lungs.

MADRID

(From Our Regular Correspondent)

Sept. 1, 1948.

Aeronautic Medicine in Spain

The National Department of Sanitation in Aviation, of which General Miguel Lafont Lepidana is the head, has important centers for teaching and research on aeronautic medicine in Madrid and in Sevilla, besides centers for either purpose in hospitals and infirmaries in several cities, and centers of aeronautic medical first aid with which all the airdromes and aviation units are provided. There are polyclinics with radiologic departments, in Zaragoza, Valencia, Valladolid, Palma de Mallorca, Las Palmas (the Canary Islands) and Tetuán.

The headquarters of the organization are in Madrid, where there are three independent centers, namely, the Academy of Sanitation, the Central Hospital and a sanatorium against tuberculosis with one hundred and fifty beds. The Center of Research on Aeronautic Medicine is now under construction in a suburban district near Madrid.

In the Academy of Sanitation the work carried on consists of teaching courses for the preparation of medical cadets and of nurses. All personnel, of this national branch has their first medical examination there for entrance to the service. After this examination all the personnel have periodic roentgenographic examinations of the lungs for tuberculosis.

In the Central Hospital there are two departments of general surgery, with Drs. Angel Garaizabal Bastos and Luis Suarez Carreño as heads of the departments. There is also a department of urology, with Dr. Martin Laborda as head. A department for surgery of the lung is to be constructed in the near future. The three complete departments for neuropsychiatry, nutrition and diseases of the digestive tract and diseases of the respiratory and circulatory apparatus are provided with departments of radiology, electrocardiography and metabolimetry. There is also an independent department of general roentgenology, with divisions for roentgen and radium therapy, which include the departments of physical therapy and electrotherapy. There are also a clinic of specialities, departments for infectious diseases and pathologic anatomy and clinical laboratories. Examinations of all aviation personnel are made every six months at the Central Hospital. The examination is carried on by specialists, and the persons showing organic disease, even if minimal, are temporarily removed from duty and may be permanently removed if the organic condition does not improve.

The Center of Research in Aeronautic Medicine, which has a building in University City, is organized in independent sections, namely, Pathologic Anatomy of Flight (Dr. Valle Jimenez, Physician Commandant), General Physiopathology of Flight (Dr. Ruiz Gijón), Physiologic Pathology of Flight (Dr. Grande Cobián) and Department of Aeronautic Medicine (Dr. López Cotarilla). The Center has two low pressure chambers, one for sudden decompression and the other for experiments on animals. The chamber for studies on human beings is used also for physiologic studies of flight personnel who have examinations at the Central Hospital.

The Medical Center of Aviation has carried on important studies on aeronautic medicine. Some of these are:

1. Studies on resistance to anoxia. These studies were carried out on two groups of 20 men each, namely, those who had altitude "training" periods by living in high mountains at least a month before starting to fly and those who had not (controls). The resistance to anoxia, at various altitudes above 4,500 meters (the limit of free normal respiration) was greater in "trained" men than in the controls. The mechanism of defense of hypoxia appeared earlier, and the reserve time for the limit altitude of 7,000 meters (time of appearance of symptomatic disorders) was longer in the former than in the latter. It is apparent from these findings that the stay of pilots in high mountains before starting to fly increases their capacity to withstand altitudes.

2. Physicians at the Center of Medicoaeronautic Research are carrying on studies on the cardiocirculatory, respiratory and sensorial changes, signs of immediate collapse. Changes of the renal function during flying were also studied (the creatinine clearance test). The results of studies on the renal function are confirmatory of previous reports concerning cases of pronounced anuria before and in the course of occurrence of collapse. The experiments carried on by these physicians confirm those reported by Scandinavian and other researchers, namely, that injection of blood of animals in the precollapse stage into normal animals causes fulminant anuria.

3. The Center of Medicoaeronautic Research is carrying on research on the effect on respiration of pure oxygen at different altitudes. Dr. Valle showed the toxic effects of oxygen under high pressure, causing lesions on the lung, alveolar desquamation, general congestion and hemorrhages of capillary vessels and of venules which originate in the hilus. There is arteriolar contraction without any arteriolar lesion. The arterioles may dilate, later on, with frank capillary and venular dilatation (an image which is opposite to that provoked by histamine in the normal lung). There is also regular dilatation of the bronchial tree, the mucosa of which is unfolded without any normal folds, and it is the seat of acute infiltration of the catarrhal type, with eosinophils, histiocytes and plasma cells ("asthma from oxygen," which may progress to asphyxia). These changes are less acute when caused by great altitudes than when caused by moderate altitudes, a phenomenon which probably depends on the relative partial hypopressure of gas in the alveoli which is a natural effect of altitude.

4. Experiments were carried on to ascertain the significance of the reticuloendothelial system in anoxia. The method used was that of the time of disappearance from the blood of vital stains (tripan blue or india ink) in predetermined periods which

during the time of observation were not eliminated through the emunctory organs. The animals breathed for a long time in high altitude atmospheres (in general, the experiments were carried on always at the critical altitude of 7,000 meters). Slight irritation of the reticuloendothelial system and increased functional activity were shown by the prompt elimination of the stains from the blood. The changes of the reticuloendothelial system were either moderate or almost unnoticeable. The results of the aforementioned experiments will be reported by the Center of Research on Aeronautic Medicine in the near future.

The Institute of Aeronautic Medicine, of which Colonel Dr. Jiménez Ontiveros is the head, is also carrying on research which will be reported in the near future.

Correspondence

ARMY MEDICAL SERVICE

To the Editor:—It seems to me that the needs for specialists, set forth in General Bliss's letter, could easily be met if the medical schools were to grant one year's leave of absence to all faculty members who were on essential lists during the war and these men served in appropriate posts in the Army during the next two years. In many cases they could be assigned to service installations within commuting distance of their homes, for at least half of their tours of duty, but all should be at least three months in the overseas installations.

During the war many of us were surprised at the disqualification of medical applicants for trivial physical defects. I was asked to enter the Navy, by the late Commander Eric Liljencrantz, and was rejected for defective vision. My vision was tested, in about thirty seconds, by an enlisted man, but that settled the matter. Why a doctor needs more than 20/20 in one eye and 20/80 in the other is a mystery. Why any doctor who can engage in practice cannot be used in the service would be difficult to explain, since dispensary duty is far less exacting. Yet many men who went through medical school as Army privates were turned down for commissions, in 1944-1946, because of "physical defects" which had in no way interfered with a seventy hour week as interns. Specialists, in many cases, are over 40 years of age and have trivial physical defects, but it should be easy to supply 800 from the group of medical school "essential list" members if the Army wants technical competence and ability to put in a full week's work, rather than some ideal of physical perfection.

William Dock, M.D., Director of Medicine,
Long Island College of Medicine, Brooklyn.

DIABETES DETECTION

To the Editor:—In response to many questions from doctors dealing with methods which may be employed to discover patients with diabetes in a community, the following statement, which should prove helpful, has been prepared. The demonstration by a series of surveys that *there are a million patients with* undiscovered diabetes in the United States and Canada is a challenge to the doctors of these countries to discover these diabetic persons early and to bring to them the advantages of the great discoveries in the treatment of diabetes in recent years. With the cooperation of state and county medical societies, local diabetes associations and all health agencies this may be assured.

In January 1949, there will be available a "kit" which is now in the process of manufacture, which will provide for doctors a method for doing a "screening" blood sugar analysis in his office in five to ten minutes. This blood sugar analysis is so arranged that it screens patients whose blood sugar levels are above or below normal, although it does not give an absolute figure for the blood sugar. However, this method developed by Dr. Wilkerson and his staff of the U. S. Public Health Service will really enable the practicing doctor to do in his office a test which will be of tremendous value in the process of screening out those patients whose glycosuria deserves further study. It will provide a technic which will give the doctor something he needs and at the same time will give great aid to the teaching of diabetes especially in postgraduate courses. In county medical societies, it does seem to me that the work of daibetes detection may be prosecuted with confidence.

Howard F. Root, Boston.

Diabetes Detection Drive Beginning in Diabetes Week, Dec. 6-12, 1948

HOW TO FIND AND HELP THE DIABETIC PATIENTS IN YOUR COMMUNITY

Ten Questions from Physicians: Answers from The American Diabetes Association

"I'll do my share," says the doctor, "but I'd like to ask a few questions about this Diabetes Detection Drive."

1. *What symptoms should suggest early diabetes?*

   Don't wait for any of the typical symptoms of diabetes
   - (*a*) Loss of weight and strength in spite of a good appetite.
   - (*b*) Increase in thirst, (*c*) frequent urination, (*d*) itching.
   - (*e*) Aching pains in the extremities, and (*f*) visual disturbances.

   The early diagnosis of diabetes can only be made with certainty by laboratory tests of the blood and urine.

2. *Who are the people with hidden diabetes? What kind of person is in this group?*

   It may be anyone regardless of race, age, sex, weight or previous state of health. It may be *you.*

3. *How can I find out if I have diabetes?*

   Have the urine tested for sugar one to three hours *after you have eaten a full meal.* Arrange for a blood sugar test if the urine shows even a trace of sugar.

4. *What laboratory findings indicate diabetes with a high degree of probability?*

   Any amount of glucose in the urine, accompanied by blood sugar values * above the following levels:
   - (*a*) Venous blood sugar
     1. By Folin-Wu method—over 130 fasting; over 200 after eating.
     2. By Somogyi method, or other method indicating true glucose value, over 110 fasting, over 150 after eating.
   - (*b*) Capillary blood sugar
     1. By Folin-Malmros method, over 140 fasting, over 240 after eating.
     2. By methods indicating true glucose value, over 120 fasting, over 200 after eating.

   When the reports are close to these values or when there is a complicating illness (for example, hyperthyroidism):

   (*a*) Repeated blood sugar tests should be secured, or

   (*b*) A glucose tolerance test performed for verification, after the illness has subsided. The sugar tolerance test should be done under normal conditions of diet; the diet for three days in advance of the test should include at least 250 grams of carbohydrate per day. The diagnosis of diabetes should not be made on the basis of one high blood sugar report alone.

5. *What laboratory findings usually rule out diabetes?*

   A venous or capillary blood sugar below the following values, 30 to 90 minutes after a meal containing the normal amount of carbohydrate, *providing the diet has not been restricted previously:*
   - (*a*) Folin-Wu (venous or capillary) or similar method, below 120.
   - (*b*) Somgyi, (venous or capillary) or other method indicating true glucose, below 90.

---

* All blood sugar values are expressed in mgs. per 100 cc. blood.

6. *When facilities for blood sugar tests are not readily available, what is the alternative?*

A blood sugar test for screening has been introduced by Wilkerson and Heftmann * which enables any physician or technician to make this test in the office or in the home. It does not show the exact level of the blood sugar; it only shows whether the blood sugar is abnormally high or abnormally low. The diagnosis of diabetes should not be made by this test alone. When it indicates high blood sugar, it must be verified by one of the standard methods. If no blood sugar tests are made, the urinalysis should be repeated frequently. If glycosuria is present, accurate blood sugar tests are essential for the diagnosis of diabetes.

7. *What can I, as an individual physician, do to aid in the Diabetes Detection Drive?*

(*a*) Test your own urine today
(*b*) Test each member of your family this week
(*c*) Make urinalysis for
  1. Every new patient routinely
  2. Any patient who has had an acute illness
  3. Obese patients and relatives of diabetics every three to six months.

ALWAYS MAKE URINE TESTS ONE TO THREE HOURS AFTER A MEAL

(*d*) See that a blood sugar test is made following every positive urine test.
(*e*) Participate in programs for such diabetes surveys as may be promoted by county or state medical societies, local, diabetes associations and the public health departments.

8. *In planning for mass surveys should an attempt be made to reach everyone in every community?*

Anyone may develop diabetes and to secure personal protection against preventable ill health, it is sound and feasible to promote the policy of a URINE TEST FOR *EVERY*-ONE EVERY YEAR. This can be accomplished if each practicing physician will average two or three urinalyses each day.

9. *If this policy of annual tests for every one cannot be achieved immediately, in what direction should efforts be aimed first?*

Tests should be sought in:

(*a*) Relatives of diabetics
(*b*) Obese individuals
(*c*) Adults over 40
(*d*) Individuals who feel below par.

10. *What methods are recommended for mass surveys?*

The American Diabetes Association recommends that arrangements for surveys should be organized only with the cooperation and participation of local, county and state medical societies.

In surveys which have been conducted in the past, the urine tests have been made by Benedict's method, the Clinitest or Galatest. The blood sugar tests have been made by the usual standard methods including the Folin-Wu and Somogyi methods.

The Wilkerson-Heftmann screening test will soon become available. It will quickly show the individuals who need a standard blood sugar test.

The Clinitest and Galatest methods for urinalysis are simple and time saving. The reagents must be fresh to give dependable results. Whenever the results are not clear cut, Benedict's test should be made.

It has been pointed out that the work of cleaning glassware can be eliminated in making urinalyses by collection of urine specimens in paper cups and by the use of Galatest.

Some mild cases of diabetes may not be discovered at the initial examination:

(*a*) Unless a test is made within 90 minutes of a full meal.
(*b*) Unless a blood sugar test is made in addition to the urinalysis.

When ideal arrangements cannot be made the minimum goal should be:

(*a*) A urinalysis for everyone at any time in the course of each year.
(*b*) A blood sugar test to follow every positive urine test.

Bureau of Investigation

"DR." C. A. C. FAIMAN SENTENCED FOR FOOD AND DRUG VIOLATION

On Friday, October 1, C. A. C. Faiman of Dallas, Texas, was found guilty by a jury of having caused the introduction of certain misbranded drug products in interstate commerce. District Judge T. Whitfield Davidson of the Northern District of Texas thereupon sentenced him to two years in jail and turned him over to the custody of the attorney general. Faiman's attorney announced that an appeal would be taken, and bond in the sum of $5,000 was set for his liberty pending appeal.

Food and Drug inspectors testified that they watched Faiman ship the unlabeled tubes containing, as an analyst testified, potassium iodide and soft soap. The consignees were doctors of medicine, one in Arkansas and the other in Louisiana. A third doctor of medicine was named party defendant, but was acquitted at the direction of the court at the close of the government's case.

Faiman, however, was also posing as a doctor in Dallas. At one time he claimed graduation and a degree from the old St. Louis College of Physicians and Surgeons, which was involved in a diploma scandal culminating in revocation of its charter in 1927. Student lists for the years 1918-1921 did not, however, include his name. On the basis of the diploma he had obtained, he sought admission to examination for a license to practice medicine in Colorado, but the Board of Medical Examiners of that state refused to accept the credentials.

Faiman was first heard from, so far as the files of the Bureau of Investigation show, in Chicago, where he was operating the "National University of Sciences." He was then known as Charles C. Faiman, although he has also posed as Charles A. Faiman and Charles Andrew Claire Faiman. He was president of the "university," at least in 1925, when a bulletin describing its facilities indicated that it boasted such departments as arts and sciences, divinity, pharmacy, pathology and bacteriology, roentgenology, public health, medicine and surgery, midwifery, embalming and mortuary sciences, chiropractic and orthopraxy, law, music and dramatic arts.

In 1925 Faiman "confessed" to having given diphtheria germs to one William D. Shepherd, who was then indicted on the charge of having murdered William McClintock, his millionaire foster son. Shepherd, however, was acquitted of the charges by a jury in Chicago. In the publicity attending the sensational trial, it was brought out that the National University of Sciences being operated by Faiman was a "diploma mill."

Faiman was next heard from in Florida in 1929. In 1921 he had obtained a license to practice medicine in that state from the old Eclectic Board, four days after the board itself had gone out of existence. A leading member of the board proved to be in the business of dispensing diplomas and licenses. This activity ended in a federal prosecution for him under the postal statutes, in which Faiman was a party defendant. He was not convicted, but his Florida license was finally revoked. In 1930 Faiman posed as a pathologist in St. Joseph, Mo. He was there for a few weeks, but departed without leaving a forwarding address.

---

* Wilkerson and Heftmann, J. Lab. & Clin. Med. **33:** 236 (Feb.) 1948. Kit will be available from Eli Lilly Co., Indianapolis, Ind.

Faiman's career in Dallas has covered at least the past ten years. That federal activity was necessary to interrupt his business is unfortunate. Cases such as his should really be local matters.

Medical Motion Pictures

FILM REVIEWS

In the Steps of the Great Physician. 16 mm., color, sound, 1,100 feet (1 reel), showing time thirty minutes. Produced in 1947 by Alan Shilla, Wai, Marathi, North India. Procurable on rental from: Missions Council, 287 Fourth Avenue, New York 10.

This film illustrates the activities of the medical staff and other hospital personnel at the Pierce Memorial Hospital in Wai, North India. While the patient is under treatment it shows his family cooking, cleaning and living on the hospital grounds.

The production is a good example of modern medicine and missionary groups working together to bring good medical care to these foreign areas. It can be recommended as a semi-entertainment film for county and state medical society meetings and for medical auxiliary groups.

The film was made by an amateur photographer whose mother was treated at this hospital. Considering the many local difficulties involved, the photography is very well done.

The following 16 mm., black and white, sound motion pictures are part of a series of five films produced in 1948 by Audio Productions, Inc., New York, for correlation with the Textbook of Healthful Living prepared by Harold S. Diehl, M.D., Dean of the Medical Sciences, University of Minnesota, Minneapolis. Procurable on purchase from McGraw-Hill Book Company, Inc., 330 West Forty-Second Street, New York 18, or procurable on rental from Y.M.C.A. Motion Picture Bureau, 206 South Michigan Ave., Chicago 4.

The Nose, Throat and Ears. 400 feet, showing time ten minutes.

Animated drawings are used to illustrate the normal functioning of the nose, throat and ears. The film clearly portrays the cause of complications arising from the use of nose drops, careless nose blowing and neglected colds. The pictorial presentation of the epiglottis in action is especially good; however, the pictorial presentation of the tonsil left much to be desired. This production is suitable for showing to high school and college students.

The Body Fights Bacteria. 500 feet (1 reel), showing time fourteen minutes.

The film opens with a picture of an exploding atomic bomb. It points out that bacteria may even be more harmful to human life than a bomb explosion. Bacilli, cocci and spirochetes are all shown, with the porcelain filter through which various viruses are known to pass. The ordinary method of growing bacteria on agar plates is demonstrated.

The defenses against bacteria set up by the skin, by the mucous membrane of the nose, throat and gastrointestinal tract, by the lymphatic system and by the blood system, both with its cells and antibodies, are shown. The development of antibodies in the blood through the natural process of having a disease is shown in animation. Artificial immunization through the inoculation of smallpox vaccine is used to illustrate active immunization. Temporary immunization against diphtheria in the presence of an already existing throat infection is demonstrated.

This film covers the subject of the body's defenses against bacteria in a somewhat elementary manner, which should be satisfactory to the average nonmedical person. It should be a useful teaching aid for college and high school students as well as other adult groups. The photography and animation are excellent

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Compensation of Physicians: Collection of Fee by Unlicensed Practitioner.—The plaintiff sued to recover money paid the defendant for certain medical services. From a judgment for the plaintiff the defendant appealed to the municipal court of appeals for the District of Columbia.

The plaintiff suffered from arthritis and went to see the defendant, who employed the title "professor" and who agreed to give the plaintiff a series of treatments at a cost of $440. According to the plaintiff, the defendant said that these treatments would cure her; according to the defendant, however, he told her that he believed that they would be of help. At any rate, the treatments, consisting of massaging and rubbing in of an ointment, were given, and the plaintiff paid $160 on account. She then refused to pay the balance and brought this action to recover that which had been paid. The defendant filed a counterclaim for the unpaid balance of $280.

The plaintiff's claim for recovery was based on the contention that the treatments administered by the defendant were in violation of the healing arts practice act, which defines "the healing art" as including "relieving, correcting or curing" or "attempting to prevent, relieve, correct, or cure any disease," and prohibits the practice of the healing art by anyone not licensed in accordance with the act. The act exempted from its provisions "the practice of massage . . . under the direction of a person licensed to practice the healing art." The evidence showed that the defendant was neither licensed, to practice the healing art nor was he licensed to practice massage. We think it plain, said the court, that the treatments by the defendent, who is neither licensed nor acting under the direction of a licensed person, were in violation of the act, whether such treatments were given in an attempt to cure or to help the plaintiff's arthritic condition.

Considering first the defendant's counterclaim for the balance of his fee, the court said that the general rule is that an illegal contract, made in violation of a statutory prohibition designed for police or regulatory purposes, is void and confers no right on the wrongdoer. Consequently, the trial court properly ruled that the defendant was not entitled to recover the balance of the fee originally agreed on. With respect to the plaintiff's claim for a recovery of the sum which she had actually paid, the defendant contended that if the contract was in violation of the statute then no recovery can be had for money paid for illegal services which have been rendered. It has long been the law, said the court, that where an action is founded on an unlawful contract, the court will not interfere to relieve either of the parties thereto in an action against the other from the results thereof. However, the court continued, if the parties are not in pari delicto, and one of them has not been guilty of serious moral turpitude, he may repudiate the contract and recover what he has paid under it; and even though the party be considered technically in pari delicto he may be permitted to recover if the law in question was passed for his protection and it appears that the purposes of the law will be better effectuated by granting relief than by denying it. In the present case the court concluded that the plaintiff could not be considered in pari delicto with the defendant, but that even if she were it was apparent that the law was passed for the protection of the public, including the plaintiff, and that the purposes of the Act would not be effectuated by permitting the defendant to retain that which he ought not to have received. The public interests, the court concluded, are best served by requiring the defendant to pay back the fruits of his illegal agreement. Accordingly the court ruled that the defendant was not entitled to recover the balance of the fee agreed on and that the plaintiff was entitled to recover the amount which she had already paid. *Rubin v. Douglas, 59 A. (2d) 690 (1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Intraocular Pressure of Normal and Glaucomatous Eyes as Affected by Accessory Light Stimuli. R. B. Zaretskaya.—p. 721.

Capillary Fragility and Rutin Therapy.—Donegan and Thomas administered rutin to 81 patients. Forty-five of these had diabetes mellitus, and the other 36 had a variety of ocular and general disturbances. Capillary fragility was found to be abnormally increased in arteriosclerosis and hypertension, to a greater extent in diabetes mellitus, and most markedly in diabetic persons with retinopathies. Rutin has been found to decrease capillary fragility, but not to normal levels in diabetic persons with retinopathies. Although no significant improvement in vision or decrease in retinopathy was observed in diabetes after rutin therapy, it may be significant that neither loss of vision nor increase in retinopathy occurred during ten to twelve months' treatment. Rutin appears to be of benefit in the treatment of Eales's disease and central serous retinopathy.

Regeneration of Corneal Stromal Cells.—Maumenee and Kornblueth point out that regeneration of the cornea has been extensively studied in the past, but, although the origin and mode of replacement of the epithelium, endothelium, and Descemet's membrane is clearly understood, there is still a difference of opinion about the origin of the corneal stromal cells. The authors describe a method for studying regeneration of stromal cells which appears to be superior to the method previously used. Their method destroys the corneal stromal cells without disrupting the corneal lamellae. It employs solidified carbon dioxide (dry ice), absolute alcohol and a solid metal rod. Freezing various sized areas of the cornea to minus 78 C. for three to five seconds produces a convenient lesion for the study of regeneration of the corneal stromal cells. These lesions do not disrupt the corneal lamellae, are not prone to secondary infection and cause little inflammatory reaction. After the lesions have healed the cornea is clear.

Corneal Tissue Research and Cell Culture.—Hoof says that the aim of keratoplasty is to create conditions whereby the host cornea will accept the transplanted material completely so that a later cloudiness, which so often develops in transplantations of the same species but of different blood groups, will not mar the end result. She reasons that if the transplant is kept alive by means of slowly growing cell culture and of the plasma content of the blood of the recipient is increased before the transplant is made, the original structure of the albumin of the transplant could be so changed that it would gradually become assimilated with the albumin of the host. Whether the corneal graft continues to live as an independent tissue or is replaced by regenerated corneal tissue of the host has never been definitely settled. The author describes preliminary experiments in tissue culture which show the possibility of growth of the parenchyma cells out of the substantia propria. They would seem to substantiate the theory that the corneal graft lives as an independent tissue within the host's cornea.

*BCG and Newer Epidemiology of Tuberculosis. K. Birkhaug.—p. 411.
*Primary Atypical Pneumonia and Influenza: Diagnosis, Prevention, Treatment. F. L. Horsfall Jr.—p. 431.
Mutational Prophylaxis. H. J. Muller.—p. 447.

BCG and Epidemiology of Tuberculosis.—According to Birkhaug, experimental studies and clinical experience prove that a spontaneous primary infection with tubercle bacilli, which renders the organism hypersensitive to tuberculin, confers a relatively significant resistance against a subsequent tuberculous infection. The first victims of tuberculous disease are tuberculin-negative persons who have escaped a spontaneous and nonprogressive primary tuberculous infection. A result of the modern trend to defer the primary tuberculous infection from childhood to adult life is an increasing tendency among tuberculin-negative persons of early adult age to contract serious clinical tuberculosis when they are intimately exposed to infection with tubercle bacilli. This trend in the epidemiology of tuberculosis has brought about a reorientation toward the use of artificial immunization against tuberculosis by means of BCG. Although there is no definite statistical proof of the effectiveness of BCG under rigidly controlled conditions in man, such evidence is highly suggestive in animal experimentation; universal unanimity obtains as to its harmlessness and near unanimity in regard to its affording almost complete protection against the clinical manifestations of postprimary tuberculosis in children and an incomplete but highly significant protection against clinical pulmonary tuberculosis in adults. The author believes that BCG vaccine should be recommended for extensive use in the United States in tuberculin-negative reactors, in groups occupationally exposed to tuberculous infection, in population groups with high mortality and morbidity due to tuberculosis and where there has been a known exposure to tuberculosis or where an exposure is likely to occur.

Primary Atypical Pneumonia and Influenza.—Horsfall lists the incidence of symptoms in 50 per cent or more of the patients with either of the two disorders. There are five such symptoms. Three of these, headache, chills and malaise, occur with approximately similar frequencies in both illnesses. Cough is much more common in atypical pneumonia than in influenza, and if cough is absent, the diagnosis of atypical pneumonia should be questioned, because these patients usually complain that cough causes more discomfort than any other symptom. Although cough occurs commonly in influenza, it is seldom distressing. The production of sputum also is much more common in atypical pneumonia than in influenza. Fever is almost invariably present in both illnesses, and nasal congestion is also common in both. Altered breath sounds, usually rough or harsh, are heard in over two thirds of patients with atypical pneumonia, but only in about 1 patient in 10 with influenza. Slight dulness is elicited in over 50 per cent of patients with atypical pneumonia but only in about 13 per cent of patients with influenza. Whereas primary atypical pneumonia occurs throughout all months of the year, influenza occurs chiefly during the winter months. The incidence of atypical pneumonia seldom exceeds 0.25 to 1 per cent, whereas during epidemics influenza may have an incidence ranging from 5 to as high as 40 per cent. The incubation period of atypical pneumonia ranges between ten and fifteen days, whereas in influenza it is only one or two days. In atypical pneumonia symptoms develop gradually; in influenza the onset is abrupt. Agglutinins which react at refrigerator temperature with human group 0 erythrocytes are found during convalescence in 20 to 80 per cent of patients with atypical pneumonia. Agglutinins against streptococcus MG also develop during atypical pneumonia in 20 to 80 per cent of patients, but are not produced in influenza. The development of antibodies against either influenza A or B viruses is demonstrable in 70 to 95 per cent of patients with influenza, but such antibodies do not develop during atypical pneumonia. There is no specific prophylactic measure which increases resistance to atypical pneumonia. The relative immunity which follows the injection of influenza virus vaccine probably is not of long duration and may not be effective against virus strains which are widely different from those present in the vaccine.

Alopecia Areata as a Conversion Symptom.—Peck cites 4 patients in whom alopecia areata occurred as the initial symptom of a generalized neurosis. In 2 the onset of alopecia areata was associated with sudden and overwhelming fright. In the other 2 it was associated with the onset of chronic anxiety. In 1 patient the mechanism seems clearly that of a conversion symptom. This same mechanism may be postulated in the other 3, as conversion symptoms are frequently seen in the ordinary traumatic anxiety neurosis and anxiety hysteria.

Quinacrine Hydrochloride in Tularemia and Undulant Fever.—During the past three years D. H. Ecke, the senior author, observed 8 patients with typical symptoms of ulceroglandular tularemia. Every case was traced to the handling of rabbits a few days before. The patients were given a supply of 1.5 grain (0.1 Gm.) quinacrine tablets with instructions to take one tablet three times a day for five days. Iodized ointment was prescribed for external application to the ulcers. Without exception quinacrine produced favorable results within one to three days, and no patient required treatment after the fifth day. These favorable results induced the senior author to try medication with the same dose of quinacrine hydrochloride (one tablet of 1.5 grains three times a day, for five days) in 4 patients infected with Brucella abortus. Here again the results were encouraging in that a recurrence developed in only 1 of the 4 patients after an interval of several years. Either streptomycin was not available or the patients could not afford the expense involved.

Hemophilia: Medical Management. — In reviewing the therapeutic management of 43 patients with hemophilia over the past seventeen years in the departments of medicine and surgery of Ohio State University Wright and his co-workers differentiate three distinct periods: The first was characterized by the use of nonspecific measures most of which aimed toward increasing the available circulating thromboplastin. These included snake venom, ovarian hormones, placental extracts and foreign protein sensitization, with horse serum or egg albumin as antigens. In the second, despite the use of these measures the continuing necessity for supportive, replacement blood transfusions during acute hemophilic bleeding episodes finally led to the recognition that, of any measure then advocated, whole fresh blood produced the most effective, even though transitory, reduction in the prolonged coagulation time. That fresh or frozen normal human plasma is just as effective as whole fresh blood was demonstrated shortly thereafter. During the third period, World War II gave great impetus to the chemical partition, isolation and therapeutic study of particular fractions from human and bovine blood plasma. As a by-product of these researches has come a so-called antihemophilic fraction of human plasma, which is bringing new hope not only for the better clinical management of hemophilia, but also for the ultimate solution of the problem of the physiology and biochemistry of this disease entity. Studies with the concentrated antihemophilic fraction of Cohn were initiated by the authors early in 1946, when material for clinical studies was made available. Selected cases from their clinical studies are presented to illustrate (1) the comparative effectiveness of the antihemophilic fraction I of Cohn versus freshly thawed plasma in promoting clot formation and (2) the possibility of successful medical management of the hemophilic patient during both elective and emergency surgical treatment.

Electric Shock Treatment in Pregnancy.—Although electric shock treatment is of value in many psychiatric disorders, its advisability in advanced pregnancy is still questioned. Of the 3 pregnant women reported by Simon 2 were treated during the advanced stage of pregnancy. In 1 of these 2 the last of fourteen shock treatments was given ten days before delivery. In the other case the last of thirteen convulsions preceded delivery by twenty-nine days. Both of these women delivered healthy babies. The other woman had received the last electric shock treatment seven months before delivery. Her infant died two days after birth. The authors believe that the death of this infant had probably no connection with the shock treatment of the mother.

Cancer of the Lung: Late Results of Operation.—Neuhof and Aufses point out that at previous meetings of the American Association for Thoracic Surgery a topographic classification of cancer of the lung was proposed and arguments were advanced to support their contention that the classification should be used as a basis for operability and prognosis. They now submit an analysis of the results of operations based on such a classification. Their observations were made on 52 patients who survived operation. The operations performed in each of three groups were: group I, twenty pneumonectomies and one lobectomy; group II, twelve lobectomies and six pneumonectomies; group III, twelve lobectomies and one pneumonectomy. In group I (cancer of the main bronchus), there were no survivals in patients with extensive regional node involvement. Involvement was limited, or absent, in the 7 patients who survived. In group II (circumscribed cancer), involvement of lymph nodes at the time of operation was rare; yet lymph node metastasis as the cause of death was unexpectedly high. Lobectomy is not curative in the presence of lymph node involvement. Despite the absence of regional node involvement, the results were poor in group III (peripherally invasive cancer), because of local recurrence, usually in the thoracic parietes. Results might be better with wider excision of the thoracic wall. The microscopic features of cancer of the lung bear no significant relation to the ultimate postoperative prognosis. The prognosis after a correctly selected operation for circumscribed cancer of the lung is better than that for cancers of the main bronchus. Lobectomy may be curative for circumscribed and peripherally *invasive carcinoma of the lung.* Good results have been achieved by pneumonectomy or more conservative operations on the basis of the topographic features of the neoplasm. Enthusiasm for surgical treatment of pulmonary cancer is justified when eradication is based on the topographic features.

Survival After Resection for Carcinoma of Lung.—Adams says that in a fifteen year period diagnosis of carcinoma of the lung was established by microscopic proof in 182 cases at the Lahey Clinic. A resection of the lesion by pneumonectomy or lobectomy was done in 56 cases. Eight of these 56 patients died postoperatively. The over-all hospital mortality *of 14.3 per cent has been reduced during the last five years* to 5.1 per cent in thirty-nine resections. Of the remaining 48 patients, 17 were operated on five or more years ago; of these 6 survived over five years and 4 are now living and well after more than five years. A patient who has a resection and survives the operative procedure has approximately a 60 per cent chance of surviving for one or more years. Thereafter, the rate of death from recurrence is directly related to the preoperative duration of symptoms for epidermoid carcinoma. In other varieties, the cell type is of greater prognostic significance. The survival rate in patients for whom lobectomy was selected has been as good as for patients treated by pneumonectomy. The absence of involved nodes increases three fold a patient's chance of being alive and well five years after resection. The cell type of carcinoma found by microscopic examination is the most important single consideration in estimation of prognosis after a resection. If the growth is undifferentiated or oat cell carcinoma in type, less than a year of life may be expected.

Eosinophilic Granuloma of Rib.—Maurer and DeStefano say that approximately 39 cases of eosinophilic granuloma have been reported to date. Only 6 of these lesions have been solitary in the rib. The authors present the case of a boy, aged 16, in whom osteogenic sarcoma of the rib was suspected. Focal osteomyelitis and giant cell tumor were also considered in the differential diagnosis. Excision of the fifth rib, transverse process, intercostal muscle and pleura was performed. A soft, yellowish red tumor mass was encountered completely replacing the normal structure in the vicinity of the angle of the fifth rib. Microscopic examination revealed a typical granulomatous appearance. The condition was diagnosed as eosinophilic granuloma of the rib. The convalescence was uneventful. The patient was well ten months later and presented no evidence of recurrence. Eosinophilic granuloma appears to be a benign lesion of bone which most commonly affects children, adolescents and young adults, especially males. Local tenderness and pain with or without swelling are common symptoms. There may be systemic manifestations including pyrexia, general malaise, loss of weight and leukocytosis with eosinophilia. It is more common for the lesion to be completely silent until discovered on the roentgenogram as a destructive process. The roentgenographic appearance of the individual lesion of bone is that of a small or large irregularly destructive radiolucent zone. *This lesion is easily confused with neoplasm and osteomyelitis.* Since the final diagnosis is not usually made until histologic examination of the tissue has been completed, one cannot know the course of a solitary lesion which closely resembles neoplasm if it were left undisturbed. Eosinophilic granuloma of bone appears to offer an excellent prognosis despite its rapid development, seemingly progressive nature and ominous roentgenographic appearance. The postoperative observations ranging from seven months to six years made by Jaffe and Lichtenstein on patients treated by excision, curettage and radiation therapy have all been encouraging. The prognosis should, however, be guarded in cases in which multiple lesions are encountered. In such situations, visceral lesions should be sought for and careful consideration given to the possibility of Letterer-Siwe disease.

*Creeping Eruption in Kansas. O. S. Walters.—p. 197.

Creeping Eruption in Kansas.—Walters says that creeping eruption, a cutaneous lesion produced in the human skin by the third stage larva of a hookworm, has been regarded as peculiar to the South, especially to the Gulf states. He describes 10 cases of creeping eruption which he observed in Kansas in the course of two years. The lesion produced by the larva is a linear, serpiginous burrow. The track is 1 to 2 mm. wide, red and raised. Vesicles may be formed along the course of the tortuous tunnel. The parasite travels from one to several centimeters a day. The area of the lesion itches intensely. Most of the patients treated by the author responded to freezing with ethyl chloride. Intramuscular injections of 0.5 to 3.5 cc. of stibophen in increasing doses were effectively used in 2 patients, in 1 of them in conjunction with ethyl chloride.

*Culpability for Delay in Management of Cancer. D. E. De Lawter.—p. 342.

Delay in Management of Cancer.—De Lawter investigated delay and culpability for delay in the diagnosis and management of cancer. The cases analyzed were obtained from records of interviews at the Warwick Memorial Clinic from 1946 to 1948. The patient was unaware that any but routine questions were being asked. The questions were as follows: 1. What was the first thing you noted? 2. When did you notice it? 3. What did you think it was? 4. What did you do about it? 5. When did you do it? 6. When did you first consult a physician or seek medical care? 7. To whom did you go (physician, radiologist, chiropractor, surgeon, etc.)? 8. What did he do about it? 9. When did he do it? 10. Was a piece of tissue removed for examination? When? 11. What did he advise? 12. Did you follow that advice? 13. Of what did the treatment consist? 14. When was treatment started? 15. By whom was treatment started? A total of 420 cases were investigated in this manner, and the impression was gained that progress is being made in reducing the delay in the diagnosis of cancer. The causes for delay between diagnosis and treatment in these cases were: (1) delay by the institute's ruling not to accept the pathologic interpretation of the biopsy obtained at another institution; (2) delay by pathology department in arriving at a diagnosis; (3) delay of specimens and reports in interdepartmental transit; (4) delay between clinic appointments and consultations because certain clinics are held only at weekly intervals; (5) delay because general physical condition of the patient would not safely permit immediate institution of treatment; (6) delay in obtaining a hospital bed or operating room for treatment, and (7) delay by patient in accepting therapy advised. The delay between completion of diagnosis and institution of treatment was excessive in 45.7 per cent of the cases studied. No case of delay was found to be specifically due to lack of finances.

*Report of Case of Stevens-Johnson Disease. I. L. Hoffman and T. E. Stone.—p. 494.

Stevens-Johnson Disease.—Hoffman and Stone point out that Stevens and Johnson in 1922 described a "new" eruptive fever associated with stomatitis, ophthalmia, cutaneous eruption and constitutional symptoms. The authors report a case in a native-born Hawaiian aged 17. The patient had a sore throat and signs of nasopharyngitis with a temperature of 104 F. He had a nonproductive cough. The patient had three previous episodes of a similar nature involving the mouth and genitalia. With symptomatic treatment the temperature became normal on the fourth day, but on the sixth day it rose to 105 F.; it slowly decreased until it became normal eight days later. On the sixth hospital day ulcerated, membranous and vesicular lesions appeared on the tongue, gingivae and buccal mucosa. These areas became confluent and involved the lips. On the eighth hospital day vesicles appeared on the skin of the genitalia, forearms and legs with occasional discrete lesions on the trunk. Severe bilateral, conjunctivitis developed which subsided in ten days. New cutaneous lesions continued to appear. These lesions started as small erythematous macules, which became edematous, later vesicular or bullous, and still later hemorrhagic or purulent. The glans penis became involved, culminating in acute balanitis. After various laboratory examinations the case was diagnosed as one of severe Stevens-Johnson type, due perhaps to hypersensitivity to streptococcic pharyngitis. Treatment consisted in administration of penicillin by injection and spray and in ointment. During the acute stage the patient was also given sulfadiazine. Vitamins were given by injection and by mouth. The authors raise the question whether cutaneous testing with streptococcus allergens with desensitization with positive allergens might ward off future attacks.

Bronchiectasis Following Aspiration of Timothy Grass.—Carter and Welch say that children often aspirate vegetable foreign bodies into the tracheobronchial tree. They report observations on 8 cases of timothy grass aspiration. These patients were observed between October 1942 and March 1947. The ages varied from 1 year and 2 months to 14 years. A well established or highly suggestive history of foreign body aspiration was obtained from 5 patients. All 5 patients had immediate symptoms. Intermittent fever was always present. Cough was prominent in 7 patients, loss of weight in 4 and abdominal pain in 1. An initial diagnosis of pneumonia was made in 5 cases. The possibility of a foreign body was suggested in only 2 of the 8 patients when first seen. When roentgenograms were obtained the diagnosis of pneumonitis, atelectasis, pneumonia or abscess was made. Prolonged symptoms ultimately led to bronchoscopy in 7 cases. In 3 of these the timothy head was recovered, but in 4 of them the foreign body was not found in spite of multiple bronchoscopies. Recovery was apparently complete in 1 patient after bronchoscopic removal of timothy. The remaining 7 required lobectomy because of bronchiectasis or pulmonary abscess. The uneventful convalescence of these 7 patients illustrate the low risk of lobectomy in young patients. Even though the presence of a foreign body cannot be established, recurrent hemoptysis from an obviously damaged lobe or known bronchiectasis should be an indication for surgical treatment when tuberculosis has been excluded.

Cardiac Patients and Travel by Air.—Schmidt outlines some of the dangers confronting patients with cardiac disease who travel by air. He believes that for some types of disturbed cardiovascular function travel by air can have serious consequences, while for other cases it may be perfectly harmless. The advice given to a patient with cardiac disease should be based on evaluation of the individual patient's cardiovascular status, with particular attention to the relative sufficiency of his coronary circulation and the adequacy of his pulmonary gas exchange and oxygen-carrying power of the blood.

*Atabrine [Quinacrine] in Treatment of Trichomonas Vaginitis. F. M. Dula.—p. 309.

Quinacrine in Trichomonas Vaginitis.—In search for a chemical agent with which to combat vaginitis due to Trichomonas, Dula was struck by the morphologic similarity between Trichomonas vaginalis and Giardia lamblia. From this he concluded that these two organisms might respond in a similar manner to quinacrine, which had been used successfully in infestations with Giardia. He began using insufflations of quinacrine (30 grains [2 Gm.]) in finely powdered boric acid (1 ounce [30 Gm.]). The cervix and the vagina were first mopped dry; then the mixture was blown into the vaginal canal through a speculum and a cotton-tipped applicator was used to distribute the powder over the entire vaginal surface. Four treatments were given at two day intervals. All final smears have been reported negative in the 6 cases so treated, but some vaginitis has persisted for several days after the negative smear was obtained. In 1 case severe chemical vaginitis necessitated discontinuation of the treatment after the second application. The 6 cases of vaginitis due to Trichomonas had proved refractory to other forms of treatment, and the condition had persisted for periods as long as five years. The author believes that the routine use of quinacrine is justified and may prove of great value in vaginitis due to Trichomonas.

Preparation of Granulating Wounds for Grafting.—Outlining the method by which large infected wounds are transformed into clean ones preparatory to grafting, Mills and his co-workers say that the usually malodorous ointment dressing is removed and a wound culture and a photograph are taken; then a complete blood count, urinalysis, blood Kahn test, determination of plasma protein, albumin and globulin and blood typing are ordered. All crusts and necrotic tissue are removed; the surrounding skin washed and shaved and a single layer of nonoverlapping 40 by 44 mesh plain sterile gauze is applied. This is followed by wet saline dressings. Evaporation and contamination are minimized by wrapping the part in sterile cellophane. The saline dressings are then changed every four hours down to the fine mesh gauze with sterile technic. The fine mesh gauze is usually left undisturbed for one week. During this interval the patient's temperature usually returns to normal, his appetite improves and the blood picture is brought back to near normal by blood transfusions. By the third hospital day the wound culture report is available, and, if this reveals pathogenic gram-positive cocci, penicillin may be added to the saline solution. If pathogenic gram-negative bacilli are reported, nitrofurazone solution may be used. Neither is recommended for routine use. On the seventh hospital day the fine mesh gauze is removed, all exuberant granulations cut down to a firm base and fresh mesh gauze reapplied and wet saline dressings resumed. By the tenth hospital day the granulating bed is usually ready for skin grafting. The authors stress the advantages of the fine mesh gauze treatment, pointing out that it allows the drainage of exudate into the overlying wet dressings which can be changed frequently and relatively painlessly. Removing the granulations prior to the day of skin grafting results in a cleaner wound, a more receptive bed and minimizes bleeding beneath the graft. Changing the fine mesh gauze two or three days prior to grafting likewise minimizes oozing from the granulating wound when the gauze is removed the day the grafts are placed. After skin grafting fine mesh gauze allows the spread of epithelium with a minimum of disturbance.

*Comparison of Nutritive Value of Egg Proteins and Their Amino Acid Content. W. C. Hess, E. H. Kramke, J. C. Fritz and H. W. Howard.—p. 552.

Antibodies in Vitamin Deficiency States.—Carter and Axelrod studied hemagglutinin production in response to inoculation with human erythrocytes in thiamin-deficient and biotin-deficient rats. A moderate impairment of antibody response was observed in both deficiencies.

Cultivation of Rickettsia in Dead Chick Embryos.—Rabinowitz and her co-workers found that chick embryos which were killed by chilling on the third day of development and were thereafter maintained at 37 C. for sixteen days still contained living cells. Rickettsia prowazeki multiplied abundantly in dead chick embryos which contained surviving cells. Since the growth period for rickettsia in dead embryos may easily be extended to sixteen days, or double the time customary in work with living embryos, even minute inoculums have a chance to multiply significantly. Inoculums too small to yield a positive smear after the usual seven days' incubation in the living embryos yielded smears containing numerous rickettsia after fourteen days' incubation in the dead embryos.

Nutritive Value of Egg Proteins.—Hess and his co-workers prepared whole egg, whole white and yolk proteins and analyzed them for nitrogen, sulfur, cystine, cysteine, methionine, phenylalanine, tryptophane, threonine, histidine, lysine and arginine. The same proteins were used in feeding experiments with young rats to determine their protein efficiency values. In addition three commercial egg proteins were tested similarly. The authors found the protein efficiency ratio of the whole white protein to be higher than that of either the whole egg or the yolk proteins. The protein efficiency ratio of the commercial whole white protein was almost as high as that of the laboratory prepared sample. The protein efficiency ratio of commercial whole egg protein was markedly lower than that of the laboratory prepared sample. The amino acid content of all the whole egg proteins was similar with the exception of the cystine content of the commercial samples, which was lower than that of the laboratory samples.

Testosterone for Women with Recurrent Breast Cancer.—Davis cites histories of 7 patients with recurrent cancer of the breast in whom he resorted to the use of testosterone propionate. He concluded that testosterone is of benefit in cases in which no further roentgen therapy can be used. None of these patients were apparently made worse by the use of this drug. It proved of value in the presence of pulmonary and particularly of skeletal metastasis. All of the women, with one exception, had a feeling of well-being and relief from pain which could not have been all psychic. It seems that, along with high voltage therapy, roentgen or surgical castration, testosterone is another weapon against one of women's most relentless enemies.

Rupture of Spleen in Mononucleosis.—Hicks reports the case of a sailor aged 18 years, in whom rupture of the spleen occurred in the presence of an unsuspected infectious mononucleosis. The patient recovered after splenectomy. The diagnosis was made from pathologic examination of the spleen, the presence of atypical lymphocytes in the blood and a sheep cell agglutination titer in the patient's serum of 1:112, which was unchanged by adsorption on guinea pig tissue (Davidsohn test). Rupture of spleen complicating infectious mononucleosis has recently been brought into prominence by a report of 7 cases from the Army Institute of Pathology. Four cases were fatal; 3 patients recovered after splenectomy. Of 3 cases reported in the literature previous to that time 2 were fatal. In 2 other previously reported cases recovery followed splenectomy. The possibility of a splenic rupture should be kept in mind in the management of infectious mononucleosis for two reasons: (1) It has carried a high mortality thus far, and (2) rupture appears to occur after trivial injury, even after palpation of the spleen.

Enhancement of Bacterial Infections by Epinephrine.—Evans and his associates point out that after the observation that an intramuscular injection of epinephrine in a man had apparently induced Clostridium welchii gas gangrene at the injection site, Cooper, in 1946, demonstrated a great decrease in the minimal lethal dose of Cl. welchii when washed baccilli were injected into the muscle of guinea pigs together with epinephrine. It was thus demonstrated that epinephrine enhances the infectivity of Cl. welchii. Evans and his associates investigated the nature of this enhancement in experimental infections with clostridia and with a number of pathogenic aerobic bacteria. They found that injection into the skin or thigh muscles of guinea pigs of 2 micrograms of epinephrine renders these tissues more susceptible to some microbial infections. The resulting enhancement of infection by strains of various pathogens tested was as follows: Clostridium septicum and Cl. welchii, 100,000 fold; Bacterium coli, Proteus vulgaris, Pseudomonas pyocyanea and Streptococcus pyogenes, 100 to 10,000 fold; Corynebacterium diphtheriae and Staphylococcus aureus, 10 to 100 fold; Bacterium subtilis, Brucella abortus, Clostridium novyi and Streptococcus pneumoniae, about 10 fold; Shigella flexneri, Shigella sonnei and Vibrio comma, 2 to 5 fold. Infections with strains of Clostridium histolyticum and Clostridium tetani were not enhanced. In the skin of the rabbit, Staph. aureas was enhanced 100 fold, vaccinia virus 10 fold and Haemophilus pertussis not at all. Epinephrine enhances chiefly infection, not intoxication. The temporary failure of mobilization of bactericides in epinephrine-treated tissue appears to be the chief factor in the enhancement of infections by epinephrine. There is some evidence of an early removal of bacteria from the injection site which is retarded by epinephrine, with a consequent increase in the severity of the local lesion. The removal of certain vital dyes is also retarded by epinephrine.

Deficiency Scrotal Dermatitis in Prisoners of War.—Frankland reviews observations on deficiency scrotal dermatitis seen in Allied prisoners of war in the Far East. From July 1 to Dec. 31, 1942, 1,371 persons were admitted to the skin ward at the main hospital for British personnel. Of these, 551 were primarily admitted for scrotal dermatitis. The first symptom noticed was an irritation of the scrotum, always worse at night. In its mildest form the scrotal dermatitis would last for only a few days and then would relapse and last days or weeks. Heavy work, heat and illness were the chief precipitating causes of the onset or a relapse. The author describes the symptoms of four different forms of the disease: the mild acute dry form, the severe chronic dry form, the chronic wet form and the ulcerated and edematous form. Associated vitamin deficiency diseases included oral lesions such as deficiency scrotal dermatitis, angular stomatitis, sore lips and sore tongue. Common cutaneous lesions were superficial desquamation on the nasolabial folds and on the skin adjacent to the pinna. Painful or burning feet and ocular manifestations such as granular cornea and retrobulbar neuritis were other manifestations of vitamin deficiency. It was noted that no cases of scrotal dermatitis occurred when the riboflavin content of the diet was maintained at a sufficiently high level. Riboflavin preparations seem to have a curative effect in cases of mild disease.

Streptomycin in Bubonic Plague.—Haddad and Valero say that in 1947 bubonic plague broke out in Haifa, Palestine. Sulfonamide drugs, especially sulfadiazine, were administered as a routine in all cases. When possible the initial dose was 2 Gm. given orally, followed by 1 Gm. every four hours during the acute stage. Later, smaller quantities were given until the bubo healed. Results were favorable on the whole, but the condition of 3 patients admitted when seriously ill deteriorated rapidly. They were given 200 or 300 mg. of streptomycin every three hours, and in 1 case it was continued for eleven days. The 3 patients recovered after this treatment, but although the effect of streptomycin on the general condition of the patients was remarkably good, the buboes appeared to be uninfluenced when treated late in the disease. This was true also of the sulfonamide drugs. In most cases incision and drainage were necessary to bring about resolution.

Fantom Limbs.—Observations by Henderson and Smyth were made in prisoner of war hospitals in Germany. Amputation was nearly always a sequel to gunshot wounds and was performed usually within the first week or two after wounding. Observations on 300 cases revealed that a fantom limb is a natural and almost universal sequel to amputation. Three kinds of sensory phenomena may appear; (*a*) mild tingling, which forms the basic part of the fantom in nearly every case and probably arises in the cerebral cortex; (*b*) stronger pins and needles induced momentarily by touching a neuroma in the stump; (*c*) occasionally, superadded sensations which may be disagreeable and painful and probably have a psychogenic basis. Special attention has been given to what is termed the "natural fantom" by which is meant the basic sensory tingling, its motor counterpart, the impression of willed movements and other features. The spontaneous tingling appears in those parts (chiefly thumb, index and great toe) having the largest cortical representation, and the belief that it originates in the sensorimotor cortex is strengthened by its close functional relationship with the motor phenomena. The willed movements also are stereotyped; they are associated with observable contraction of the appropriate muscles in the stump, and their behavior reflects the fundamental importance of sensation in initiating and controlling voluntary movements. The fantom can be induced and intensified by reflex factors (for example, micturition) acting centrally. The behavior and evolution of the "natural fantom" is as if the related cerebral centers were for a time in a state of heightened activity, the later subsidence of which results in telescoping of the fantom and its eventual fading from consciousness, and perhaps also in the disappearance from subconscious levels of its neuronal patterns. Unusual superadded sensations sometimes appear which are peculiar to the patient and are believed to be psychogenically determined from the highest cerebral level. The authors stress that a fantom cannot be considered as a single entity, for its manifestations may be derived from three levels in the nervous system (psychogenic, sensorimotor cortex and peripheral nerve). It is important before operating to determine to which of these the patient's complaints are most attributable. Peripheral operations on the stump, apart from neurectomy for a sensitive neuroma, usually have no effect on the fantom.

Posthepatitis Cirrhosis.—Sherlock says that although acute hepatitis is normally followed by complete recovery, she has observed 9 patients in whom hepatic cirrhosis could be related to a preceding acute hepatitis. In 6 the hepatitis was of the simple "infective" type; in 3 it was of the "serum" variety following arsenotherapy for syphilis. The 9 patients have been followed up to five years from the development of the cirrhosis. The results of serial aspiration liver biopsies and hepatic function tests have been correlated with the clinical course of the disease. In 3 patients the hepatic lesion was well compensated and produced no symptoms, and hepatic cell necrosis was not histologically demonstrated. In 2 patients hepatic cell necrosis and degeneration were prominent; there was slight jaundice; abnormalities were found in most of the hepatic function tests. One patient died of hepatic failure. In 4 patients hepatic fibrosis was prominent and the symptoms and signs were those of portal circulatory obstruction; biochemical changes were slight or absent. Two patients died of gastrointestinal bleeding. Although the 9 cases of posthepatitis necrosis were detected in liver biopsies on 120 patients with hepatitis, this does not reflect the true incidence of this complication, since the present group is partly selected.

Bronchiectasis Simulating Chronic Bronchitis.—Wearing says that in 46 of 214 patients with symptoms suggesting chronic bronchitis bronchography revealed bronchiectasis. In 26 of the 46 cases in which bronchiectasis was discovered there was a past history of pneumonia. Pleurisy had occurred alone in 2 cases. Treatment in a sanatorium had been received by 3 patients, but no tubercle bacilli were found. Productive cough and dyspnea were the presenting symptoms in all 46 cases. Secondary symptoms were pain in the chest, sweats, loss of weight and hemoptysis. The cough was intermittent, but except in the winter months it was not severe enough to cause disability. Diminished respiratory excursion was general. There were 8 cases with clubbing of fingers. The signs and symptoms in the 46 patients with bronchiectasis in no way differed from those in the 168 patients with chronic bronchitis. There were 31 cases of cylindrical, 3 of varicose and 12 of saccular bronchiectasis. The appearances of cylindrical bronchiectasis seen in the plain roentgenogram were not sufficiently characteristic to enable a firm diagnosis to be made. Bronchography is essential to confirm and show the extent of the bronchiectasis. The bronchi in unresolved pneumonia at first undergo reversible mechanical dilatation, which may later be rendered irreversible by secondary infection of the bronchial wall. A bronchus may remain dilated for several months and yet be capable of returning to its original diameter.

Id.: III. Duration of Immunity Against Diphtheria Following Vaccination as Compared with that Following Clinical Disease and Carrier State. B. Vahlquist and G. Hackzell.—p. 149.

Duration of Immunity After Vaccination with BCG.—Walsz-Höckert gave tuberculin tests to 1,702 children who had been vaccinated with BCG from six months to eight years before. Half of those tested were less than 3 months old and three fourths less than 3 years of age when first vaccinated. The test reaction was judged as negative when a Mantoux test with 1 mg. did not produce a 10 by 10 mm. area of redness and infiltration within seventy-two hours. The tuberculin sensitivity had disappeared after two to three years in 10 per cent of the children and after five or six years in about 20 per cent. A tuberculous superinfection definitely reacts on the tuberculin sensitivity. In order to insure the protective effect of BCG, Wallgren had suggested that tuberculin tests be carried out at least at 3, 7, 10, 15 and 20 years of age. A tuberculin test every year or every other year provides greater certainty. Of the 1,702 children followed up in 6 primary tuberculosis developed. In 5 cases the disease had an extremely benign course. These 6 comprise 5.5 per cent of the 108 children who were definitely exposed to virulent tuberculous infection. No deaths occurred.

Decrease in Immunity Against Diphtheria.—Vahlquist says that during the years preceeding World War II the frequency of diphtheria was low in many countries of Europe. Among the exceptions were England and Germany. In Germany it was not only high but steadily increasing. During the war there was over the entire continent a general increase in diphtheria. The heavily infected German troops, often carrying diphtheria, probably played an important role in transmitting the disease to the populations of occupied countries. Other factors have been of decisive importance. The results of Schick tests and of antitoxin determinations in Sweden and other European countries clearly demonstrate that the situation in regard to natural immunity against diphtheria is most unsatisfactory. In Sweden the number of Schick-negative persons among nonimmunized adults does not exceed 10 per cent. As a consequence the newborn only infrequently demonstrate that passive immunity which was formerly assumed to be the rule. In spite of the unfavorable immunologic situation an epidemic of diphtheria in Sweden during the war rapidly subsided. Large scale immunization contributed to this outcome.

*Action of Cocaine Against Fatigue and Habituation to Coca in Peru. F. Cabieses Molina.—p. 316.

Coca Chewing in Peru.—The author reviews the literature on coca chewing in Peru, a problem that concerns more than 15,000,000 Andeans. He reports his own observations on the physiology of the Andeans. Much speculation on the toxicity of coca has been made. The conception of the toxicity of coca is erroneous, since it is based on the observations on the toxicity of cocaine when administered by parenteral route to persons living at sea level. In judging the toxicity of coca for the Andeans several factors must be considered: The Andeans constitute a climaticophysiologic variety of the human race. They live at altitudes between 12,000 and 17,000 feet (3,658 to 5,182 meters). They depend on half as much oxygen in the atmosphere as is available in the atmosphere of persons living at sea level. They are not great eaters, but are strong and athletic. Their sympathetic nervous system is constantly at a high tonus. The p_H of their blood is near the limit of alkalinity. Their reactions to drugs stimulating the nervous system are quite different from those of peoples at sea level. There is a direct relationship between altitude and the percentage of coca chewers. The higher the settlement of the mountaineer population the greater the percentage of coca chewers. Coca chewers consume a daily dose of coca which varies between 42 and 91 mg., a dose which is atoxic when administered by mouth. Chewing lasts for several hours; consequently the alkaloid enters the blood in extremely small doses. Cocaine is destroyed in the liver before passing to the blood. The alkalinity of the blood is another factor in destroying the alkaloid. Although definite conclusions cannot be reached, the following facts are obvious: Coca has a favorable effect on fatigue and on metabolism of respiration. The Andeans have a racial resistance to the drug, which is both harmless and necessary for them at the great altitudes of the Andes. There is no habituation to coca chewing. The custom is abandoned when the Andeans work at sea levels. Coca chewing does not cause any degeneration of the race.

Transition of Chronic Epidemic Hepatitis to Hemolytic Jaundice.—Voit points out that Kalk in a recent report on various conditions resulting from the chronic form of epidemic hepatitis suggested that this hepatic disorder may terminate in a hemolytic jaundice. On the basis of his own observations and those of his associate, Gerstenberg, Voit is inclined to accept Kalk's suggestion. The investigation of blood changes in patients who had had hepatitis some time before but who had occasional recurrences of jaundice revealed that persisting urobilinuria and indirect bilirubinemia were always accompanied by a reduction in the resistance of erythrocytes. The hemoglobin metabolism was investigated in 4 cases, in which clinical signs of impaired hepatic function were no longer present, but in which enlargement of the spleen, decrease in the resistance of erythrocytes and indirect bilirubin reaction suggested transition into hemolytic jaundice. The results obtained indicate that transition of chronic epidemic hepatitis into hemolytic jaundice is highly probable.

*Thiouracil and Acute Atrophy of Liver. E. Trucco, J. Argonz and M. Gambin.—p. 55.

Ventrical Paroxysmal Tachycardia.—Arrillaga and Soldati report clinical and electrocardiographic observations on 6 instances of paroxysmal ventricular tachycardia in 4 patients. The paroxysms were controlled three times in one patient and once in another patient. In both cases the so-called post-tachycardic electrocardiographic syndrome, consisting of depression of the S-T segment, negative T wave and, less frequently, enlargement of the Q-T interval, was observed. The post-tachycardic syndrome assumed different characteristics, depending on the direction of the electric axis during the paroxysm, that is, on the location of the focus originating the ectopic stimuli. The syndrome was reversible in a short time in one patient. It was related neither to the duration of tachycardia nor to the previous existence of organic cardiopathy. In one patient the syndrome persisted for more than two months, probably due to ischemia of variable intensity in the myocardium. Practically all drugs known to be of value in the condition were resorted to in the treatment of these patients. Quinidine injected intravenously was the only effective drug. One patient who did not react to quinidine in large doses reacted favorably to intravenous injection of 0.50 Gm. of quinidine when the injection was given one hour and a half after an intravenous injection of 4 cat units of digitalis. A large percentage of patients with paroxysmal ventricular tachycardia do not have organic heart disease before the attack, but the disease may develop afterward. The absence of heart disease before the attack and the duration of the attack do not necessarily modify the grave prognosis of paroxysmal ventricular tachycardia.

Thiouracil and Acute Atrophy of the Liver.—The authors report a woman with exophthalmic goiter who was given thiouracil as preoperative treatment. The drug was administered in doses of 0.60 Gm. for seventeen days and in doses of 0.20 Gm. for eight days, a total of 11.80 Gm. being administered in twenty-five days. The surgical intervention did not present any difficulty, and the postoperative stage was passed without complications. Eight days after the operation the patient exhibited mental agitation and confusion. She died on the thirteenth day after the operation. Necropsy revealed acute yellow atrophy of the liver.

*Cowpox. W. Kortmann.—p. 1158.

*Epidemic of Cowpox After Vaccination. R. J. Hamburger.—p. 1161.

Cowpox.—Kortmann presents the case of a man, aged 50, who presented symptoms which were finally identified as caused by cowpox infection. He had had contact with cows which had cowpox. A sulfonamide preparation was given in order to counteract the secondary infection. Recovery was uneventful. After this case the author observed a number of other cases of infection with cowpox in milkers. These patients had either not been vaccinated at all or they had been vaccinated more than twenty years before.

Epidemic of Cowpox After Vaccination.—Hamburger reports a family in which 5 persons became ill in a comparatively short time. The oldest son in this family had been vaccinated while in military service. He had felt rather ill and was given a furlough when he had not yet completely recovered. He helped with the milking, and within a week all 27 cows contracted cowpox. Lymph obtained from these cows was found to contain vaccine virus. The persons who came in contact with the animals, including 2 milkers who came from outside the family group, exhibited symptoms indicative of cowpox. The disorder took a favorable course in all the patients.

*Ovarian Abscess. T. J. van Sante.—p. 1227.

Ovarian Abscess.—Van Sante investigated all patients with pathologic processes of the uterine adnexa that had been treated at his hospital between 1930 and 1946. The total of 944 cases of adnexitis included 120 cases of a tuberculous nature. Of the 824 nontuberculous infections, 467 were treated conservatively; of 357 patients who were operated on, 115 were found who had an ovarian abscess, and 2 additional ovarian abscesses were found at necropsy in women who had not been operated on. Thus ovarian abscesses accounted for 14.2 per cent (117 of 824) of the nontuberculous infections of the adnexa. The etiology of the ovarian abscess differs somewhat from that of pyosalpinx. Streptococci, staphylococci or colon bacilli are generally found. The abscess frequently develops by continuation, and a recently ruptured follicle often plays an important part in this process. Infection by the hematogenous or lymphogenous route is much less frequent. As regards treatment, the pyo-ovarium differs from the pyosalpinx in that it is less responsive to conservative treatment and generally requires surgical intervention.

Mixed Tumor of Mammary Gland. R. Anda.—p. 1128.

Adenoma Tubulare Testiculare Ovarii.—Anker says that adenoma tubulare testiculare ovarii is the least common of the ovarian tumors called arrhenoblastomas, with more or less hormonal action ascribed to interstitial cells of the same appearance and the same biologic action as the Leydig cells in the testes. His patient was a primipara aged 34, with oligomenorrhea and, in the last nine months, amenorrhea, slight virilization in the form of growth of hair of masculine type and vague pain on the right side of the abdomen. A solid tumor of the size of a hen's egg was removed from the right ovary and found to be a typical adenoma tubulare testiculare. The menses returned four weeks after extirpation of the tumor. The abnormal growth of hair disappeared. After about a year the patient gave birth to a healthy child. This is believed to be the tenth case reported in the literature.

Serum Proteins in Diseases of Heart.—Biörck and his associates studied serum proteins in 147 cases of cardiac disease and found that several factors play a part in protein metabolism and determination of the serum protein. The presence of hepatic injury seems to be important. Low serum protein values, low total protein and low protein-globulin ratio characterize heart disorders with hepatic injury. When compensation occurs the serum protein is often increased independently of whether special measures are taken to increase the serum protein. Simultaneously with the process of compensation a transitory increase in sedimentation reaction often appears; the cause is unknown. Although the effect of the protein balance on special protein administration in uncompensated cases cannot always be registered by the serum protein value, it seems to be advantageous. The protein administered, however, should as far as possible be free from sodium ions.

*Research on Pathologic Physiology of Amputation Stumps. Study on Spatial Modifications of Fantom Limbs. A. Jung.—p. 275.
Amenorrhea and Ascensus Uteri. H. Vignes.—p. 281.

Spatial Modifications of Fantom Limbs.—Jung studied 50 amputees, 27 of whom had a precise notion of the length of their fantom limbs. On the average, the length of the fantom limb is as much more considerable as the level of the amputation is nearer to the root of the limb. The fantom becomes shorter as a rule when a weight is attached to the arm or to the forearm bent at a right angle. The fanfom becomes shorter or longer when the weight has been attached to the extensor side. At rest the fantom may have the tendency to adopt the length of the prosthesis. At work or if weight has been attached, the fantom becomes shorter. Procaine hydrochloride infiltration of the skin or of the muscles of the stump shortens the fantom. Infiltration of the stellate ganglion on the side of the amputation lengthens the fantom, while infiltration of the stellate ganglion on the opposite side shortens the fantom. In persons with amputations on both sides, infiltration of the stellate ganglion lengthens the fantom of the same side and shortens that of the opposite side. It is suggested that the infiltration of the stellate ganglion produces vasodilation in the extremity of the same side and vasoconstriction of the centers of the opposite extremity because of the crossing of the cerebrospinal fasciculi. The peripheral vasodilation therefore seems to have an opposite effect to that of the cerebral centers. Infiltration of the stellate ganglion in persons whose upper extremity has been amputated may be followed by a sensation of relaxation which has a calming effect on the patient. In persons with amputation on one side this improvement is obtained independently of the side of the infiltration of the stellate ganglion, while the effect is bilateral in patients with amputations on both sides. The sensation of peripheral heat occurs only on the same side as that of the infiltration of the stellate ganglion. In some instances the "lengthening" of the fantom obtained by the infiltration of the stellate ganglion may give the patient the impression of working with his fantom hand. The application of weight to the lower extremities shortened the fantom limb in some instances and lengthened it in others. The infiltration of the skin, as a rule, shortened the fantom. The infiltration of the stellate ganglion of the opposite side shortened the fantom limb. Lumbar infiltration on the side of the amputation and infiltration of the stellate ganglion of the opposite side improved considerably the walking of some of the amputees with artificial limbs and gave them the impression of walking with their own feet.

*Laurence-Moon-Bardet-Biedl Syndrome: Case. A. Bruna de Einis and D. Pupo Nogueria.—p. 1.

Laurence-Moon-Bardet-Biedl Syndrome.—The authors report a typical case of Laurence-Biedl syndrome in a girl 17 years old. Consanguinity of the parents and ancestors and heredity were ruled out. Administration of thyroid in daily doses of 0.1 mg. for ten consecutive days followed by ten days without therapy for several months normalized the metabolism but had no influence on the syndrome. Roentgen examination of the head showed a normal sella turcica of increased size. Administration of thyroid for some time resulted in an abundant elimination of gonadotropin in the urine. These facts show that the syndrome is not of hypophysial origin. The authors believe that the syndrome and the congenital malformations associated with it are due to defects of the germ plasm.

*Effect of Infiltration of Pneumogastric Nerves on Pains from Gastroduodenal Ulcers. J. Warter, A. Fitzenkam, A. Lévy and J. Rouillard. —p. 127.
Tomographic Study of Aorta: Its Importance for Differential Diagnosis of Aortic Dilatation from Mediastinal Neoplasm. R. Even and J. Lecoeur.—p. 128.
Tomographic Exploration of Area of Hilus in Adults. R. Jeanneret. —p. 130.

Injection of Pneumogastric Nerves for Gastroduodenal Ulcer Pain.—Warter and his co-workers treated 18 patients with pain from gastroduodenal ulceration by injecting 10 cc. of a 1 per cent procaine hydrochloride solution at the level of the vascular-nervous bundle of the neck and of the sixth cervical vertebra within the sternocleidomastoid muscle. One hundred and eighteen infiltrations were made. In the majority of the patients infiltration on the left side was sufficient to control the pain. Bilateral infiltration was required only in the most refractory cases. Relief of pain was definite in all patients. In 9 it was immediate and in 4 it occurred within several minutes. In 3 patients there was only little improvement. The infiltration was ineffective in 1 case of a gastric ulcer of the posterior wall, and one single injection, made at the left side, was ineffective in 1 patient with duodenal ulcer. In patients who were benefited by the treatment the relief from pain lasted for six to eight hours. Ten of the patients had a definite simultaneous sensation of heat at the level of the epigastrium. In 2 patients, the abdominal reflexes were diminished before the infiltration, but were restored to normal immediately after the infiltration. Paralysis of the larynx did not occur in any case, but nearly all patients presented mild tachycardia. The main effect of the infiltrations is on the sensory fibers of the pneumogastric nerves.

Book Notices

The Acute Bacterial Diseases: Their Diagnosis and Treatment. By Harry F. Dowling, M.D., F.A.C.P., Clinical Professor of Medicine, George Washington University, Washington, D. C. With the collaboration of Lewis K. Sweet, M D., Chief Medical Officer in Pediatrics and Infectious Diseases, Gallinger Municipal Hospital, Washington, D. C., and Harold L. Hirsh, M D., Assistant Professor of Medicine, Georgetown University, Washington, D. C. Cloth. Price, $6.50. Pp. 465, with 55 illustrations. W. B. Saunders Co., 218 W. Washington Sq., Philadelphia 5, 1948.

This monograph emphasizes the diagnosis and treatment of bacterial infections and the necessity of making a diagnosis on an etiologic basis. An attempt has been made to present the latest specific antibacterial agents used in the treatment of various infections. But, as with other similar projects, by the time publication takes place, rapid advances in therapy have occurred, so that statements applicable six months or a year before are already outdated.

Part I is concerned with the general phases in the diagnosis and treatment of infectious disease. The value of the illustration on "the administration of specific antiserum" on page 33 is diminished because of the fine print. This also applies to the illustrations on pages 63, 85 and 97. The principles of sulfonamide therapy are reviewed. Sulfonamide compounds are given as the drugs of first choice for plague, but recent developments show that streptomycin occupies first place. A survey of therapy with penicillin and streptomycin is then presented. Key references to pertinent literature are cited throughout. Part II considers the diseases caused by cocci. The discussion of pneumococcic infections reflects Dr. Dowling's considerable knowledge of the subject. The reviewer does not agree with his dose schedule of penicillin for pneumococcic pneumonia as given on page 117. He would prefer to use crystalline penicillin in an aqueous solution in doses of 50,000 to 100,000 units every eight hours rather than 15,000 units every three hours, and he does not employ oil and wax preparations of penicillin for an infection as recommended by Dr. Dowling throughout the monograph. Under streptococcic diseases, many will disagree with the recommendation that active immunization against scarlet fever is limited to children. Many do not believe that children should be immunized. The recommendation that subacute bacterial endocarditis should be treated with 300,000 units of penicillin during each twenty-four hour period by continuous intravenous or intramuscular infusion is at variance with practice in most clinics. An unnecessary amount of space has been devoted to gonococcic infections. Part III is a consideration of diseases caused by bacilli and includes a survey of typhoid, Salmonella infections, Shigella infections, brucellosis and acute tuberculosis. The chapter on pertussis by Dr. Sweet is particularly informative. Other bacillary diseases discussed include Hemophilus influenzae infection and tularemia. Part IV presents bacterial diseases caused primarily by exotoxins. This includes an excellent section on diphtheria.

This monograph is recommended to practitioners and students. With the exceptions noted, the illustrations, some in color, are appropriate and clearcut. An outstanding feature is the references to the medical literature appended to each chapter. The volume has a good index. It probably is impossible for any author of a monograph to keep abreast of the rapid advances in antibacterial therapy. However, no serious mistakes will be made if the recommendations in this book are followed.

The Healthy Hunzas. By J. I. Rodale. Cloth. Price, $2.75. Pp. 263, with illustrations. Rodale Press, Emmaus, Pennsylvania, 1948.

Popular interest in food-health relationships as influenced by the soil in which the food was grown began in this country in 1921, when the great English physician Sir Robert McCarrison delivered the Sixth Mellon Lecture at the University of Pittsburgh, on "Faulty Food in Relation to Gastrointestinal Disorders." The salient points of this lecture centered around McCarrison's observation on the marvelous health and robustness of the Hunzas, who dwell in a valley on the northwestern border of India, where Afghanistan, China and Russia converge. These observations were given wider circulation on the part played by the quality of the soil in food-health relationships by Sir Albert Howard, an orthodox agricultural scientist who became convinced from his work in India that chemical fertilizers in the main only "blew up" the plant at the expense of its health and of its nutritive values; that what we have been getting since the introduction of chemical fertilizers around 1860 has been volume and not value, and that the only kind of fertilization that was safe and health-producing was the composts.

The author, who is also the author of "Pay Dirt" and editor of the magazine *Organic Gardening*, has collected material in shape of numerous books and articles dealing with Northwest India. In addition, he has exchanged many letters with the present ruler, the Mir of Hunza, who is well informed about what is said of his people in the outside world.

This book, however, was written to interest the public in a theory of agriculture as it relates to the health of plants and animals who live on them. As such it is one of a dozen which have appeared in the last fifteen years designed to convert the reader to "organics." This and many of the others have been dressed up with the trappings of a cult according to ancient formula so well known to the medical historian: "One cause, one remedy, one master, one set of facts set forth in the gospel." This book, then, becomes a commentary on the "gospel."

Stripped of its mysticism, there is much that is of vital importance in this book to the health of our people. As the population of the world increases 20,000,000 souls each year and more, and the land becomes increasingly depleted, the problem facing the world is not so much how to cure disease, or even to prevent it, as it is to keep the people in robust health. Read with a judicial eye and with a mind trained to detect fallacies of cultism, this entertaining book can supply physicians with many important facts and suggestions.

Diagnostiske og terapeutiske problemer ved ferris undulans. Af Poul Mogens Jersild. [Diagnostic and Therapeutic Problems in Undulant Fever.] Denne afhandling er af det lægevidenskabelige fakultet antaget til offentligt at forsvares for den medicinske doktorgrad. With an English Summary. Paper. Pp. 156, with 3 illustrations. Ejnar Munksgaard, Nørregade 6, København, K, 1942.

This volume is an excellent summary of the problem of the diagnosis of human brucellosis by an authority in Denmark. Jersild considers first diagnostic tests for brucellosis. He points out that complement-fixing antibodies in the serum may make a delayed appearance, compared with agglutinins for Brucella, and they may persist longer in the blood than agglutinins. He concludes that the agglutination test is a highly reliable diagnostic test for active disease. The complement fixation reaction is more likely to be positive in patients that have had the disease in the past. In discussing the cutaneous test, he believes that the reaction is specific, and expresses either an active or past infection. Ten per cent of the adult population in a medical ward in Copenhagen had positive reactions, whereas less than 1 per cent of children gave positive reactions. According to Jersild the cutaneous test is not a reliable means for diagnosing active brucellosis. Brucella abortus is the only species of Brucella which has been isolated from patients in Denmark. He has never encountered a positive blood culture in a patient with negative seroreactions, which is at variance with the experience of some persons in this country. The author has been interested in the opsonins for Brucella found in normal persons and those with proved brucellosis. He believes that normal opsonins can be distinguished from immune opsonins by the use of anticomplementary serum obtained from patients with hyperglobulinemia; i. e., multiple myeloma. In discussing chronic brucellosis, he states that he has not been able to correlate brucellosis with Hodgkin's disease. In summary, the diagnosis of acute or chronic brucellosis is unequivocally established by isolation of Brucella from the patient. The next most reliable procedure is the agglutination reaction. The opsonocytophagic test and the cutaneous test are most reliable for epidemiologic studies, and of little aid in the diagnosis of the sporadic case. The reviewer is in agreement with his interpretation of procedures used in the diagnosis of human brucellosis. Unfortunately, too often the diagnosis is based on a vague set of symptoms and a positive reaction to an intradermal test. If blood cultures remain sterile and repeated agglutination tests are negative, one must seriously doubt the presence of active disease.

Jersild concludes his monograph with a discussion of the use of sulfanilamide in the treatment of undulant fever. The drug appears to shorten the duration of the illness, but one cannot be too enthusiastic about the results.

He has appended a partial survey of the literature, especially references to publications which have appeared in the foreign literature. The brief monograph represents a sound discussion of the diagnosis of brucellosis.

Contribuição ao estudo da alergia infratuberculinica na infância. Por Homero Braga. Tese apresentada para o concurso de professor catedrático de clinica pediátrica médica e higiene infantil, da Faculdade de medicina do Paraná. Paper. Pp. 140, with 6 illustrations. Empreza gráfica Paranaense Ltda., Curitiba, Brazil, 1941

This is a report of a study among contact children in Brazil concerning the tuberculin reaction. The study is based on the findings of Willis and Saenz, who concluded that in the guinea pig the tuberculin reaction based on the persistence of the allergic state could be remobilized by the inoculation of tubercle bacilli—a condition termed by Willis as "latent" allergy. Saye and Assis verified this with BCG following primary vaccination in children and the anallergic state reactivated by revaccination. Assis in children and Rosenberg in adults noted the effect of tuberculin injections in reactivation. This was called "alergia infra-tuberculinica" by Assis (infratuberculin allergy). Braga studied 134 children and found that 107 (79.85 per cent) had positive reaction to tuberculin, while 27 (20.14 per cent) had negative. The 27 with negative reaction were studied as having infratuberculin allergy by administration of 0.1 mg. dead BCG intradermally; and, of these, 22 proved to possess infratuberculin allergy, while in 5 the allergy could not be verified. The author classified these 5 as 3 doubtful and 2 negative, however. The author suggests that a state of residual allergy (or anallergy) can be activated or reinforced by inoculation with a complete antigen. He stresses the quantitative values or grades of the state of allergy, which he suggests as weak, medium or marked as determined by the features of the reaction. The constitutional state of the children appeared to influence the intensity of nonspecific reactions. There was no absolute correlation between the intensity of the allergy and the roentgenologic picture. In some of the children with infratuberculin allergy correlation could be made with the increased resistance to the infection and its evolution.

Psychiatry in a Troubled World: Yesterday's War and Today's Challenge. By William C. Menninger, M.D., General Secretary, The Menninger Foundation, Topeka, Kansas. Cloth. Price, $6. Pp. 636. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

The author of this book is the president of the American Psychiatric Association, the American Psychoanalytic Association and the Central Neuropsychiatric Association, in addition to his duties as chairman of the Group for the Advancement of Psychiatry and general secretary of the Menninger Foundation. He has accepted these honors modestly but not lightly. He is conscientious and fearless in his administrative duties as well as in his attitudes and beliefs.

The author's background of training and experience, particularly as Chief Consultant in Neuropsychiatry to the Surgeon General of the U. S. Army, has fitted him for the presentation of this comprehensive book. The reader is given a first hand picture of the actual situation and condition of psychiatry in this country at the beginning of World War II, and the obstacles that were necessary to overcome to reach a maximum of efficiency with inadequate personnel and inadequate organization. The author has outlined many of the lessons which psychiatry learned the hard way during the war and how to apply that learning to the postwar world.

Dr. Menninger points out that the war emphasized that psychiatry, to reach its full usefulness, must take three important forward steps: Research activities must be increased; the great need for more and better trained psychiatrists must be filled, and psychiatry must be presented to the public in such a way that there will be genuine, intelligent understanding.

This book is thorough, well written and easily understandable. Whether you are a psychiatrist, physician, psychologist or layman, you can profit by reading this book, as well as some of the excellent reference material.

An Evaluation of Non-Directive Psychotherapy by Means of the Rorschach and Other Indices. By George A. Muench, Assistant Professor of Psychology, University of Louisville, Louisville, Kentucky. With a foreword by Carl R. Rogers, Professor of Psychology, University of Chicago, Chicago. Applied Psychology Monographs of the American Psychological Association No. 13. Paper. Price, $2. Pp. 163. Published for the American Psychological Association by Stanford University Press, Stanford University, California; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1947.

This monograph presents another attempt at shortening psychotherapy by the method called nondirective psychotherapy. Although the author warns against evaluation of the results in any form of psychotherapy, he goes ahead to evaluate his process even without allowing a lapse of time after the termination of the therapy. It is well known that most of the psychoneuroses show some improvement after a certain length of ventilation (confession) with a nonjudgmental therapist. This is usually referred to as abreaction. It has also been established that some patients improve temporarily as a way of exhibiting gratitude to their therapist. In reading the case histories in the monograph one reads almost nothing about what has been said by the therapist, and the impression is left that the process consists almost entirely of self analysis in the presence of an objective listener. This monograph may prove interesting to any one desiring to examine all the different approaches to brief psychotherapy, but it is of doubtful value to the student or the well informed psychotherapist.

Klinisch-praktische Bewertung des Elektrokardiogrammbefundes. Von Privatdozent Dr. Oskar v. Zimmermann-Meinzingen, Vorstand der I. Medizinischen Abteilung der Krankenanstalt Rudolfstiftung, Wien III. Band I, Wiener Beiträge zur inneren Medizin, herausgegeben von Hanns Fleischhacker. Boards. Pp. 227, with 136 illustrations. Wilhelm Maudrich,, Spitalgasse 1B, Vienna IX/2; Grune & Stratton, Inc., 381 4th Ave., New York 16, 1948.

In publishing this monograph the author had as his purpose the brief presentation of the meaning of the electrocardiogram in clinical practice in simple language suitable for the medical student and the general practitioner. In the opinion of the reviewer, the author fails in these purposes because the presentation is not simple, and he assumes that the reader for whom it is intended has a greater knowledge of electrocardiography than he presumably has.

The first section, which deals with the role of the electrocardiogram in diagnosis, the clinical circumstances indicating the need of recording the electrocardiogram, what is to be expected clinically from the electrocardiogram and the circumstances in which the electrocardiogram alone is diagnostic, falls short of the mark.

The second section deals with particular arrhythmias and electrocardiographic contours. The part on arrhythmias is fairly adequate, but the part dealing with the contour of the electrocardiogram is not acceptable by modern standards.

The illustrations in the book are poor and the author is apparently poorly informed of recent developments outside of his provincial limits. For example, on page 12 he has the impression that the Mayo Clinic is in Boston!

So many books have appeared recently on electrocardiography that the time has come when no others should be published unless they serve to fill a gap. This monograph fails to do so.

An Introduction to Physical Methods of Treatment in Psychiatry. By William Sargant, M.A., M.B., M.R.C.P., Physician, Maudsley Hospital, London, and Eliot Slater, M.A., M.D., F.R.C.P., Physician in Psychological Medicine, National Hospital, London. With a chapter on Treatment of the Epilepsies by Denis Hill, M.B., M.R.C.P., D.P.M., Physician in Psychological Medicine, King's College Hospital, London. Second edition. Cloth. Price, $3.50. Pp. 215. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

This is a welcome second edition. The book contains an addition in that it has a chapter on the treatment of epilepsy. There are eleven chapters consisting of two chapters on treatment with insulin in schizophrenia and modified insulin therapy in various syndromes. There is a chapter on convulsive therapy. These three chapters are detailed adequately with all indications and contraindications. Through all this, one notices a welcome conservative attitude. The chapter on epilepsy is fairly well detailed. Other chapters consist of chemical sedation and stimulation; the technic of continued sleep treatment; use of drugs in psychotherapy; diet; vitamins and endocrines. The chapter on prefrontal leukotomy is in adequate detail, and again there is the welcome conservative attitude which is lacking in many publications.

The treatment of general paralysis includes malaria and penicillin therapy. However, nothing is said of the use of typhoid vaccine and other physical agents. The last chapter is one on the relationship of psychology to somatic treatment. There is a short bibliography at the end of the book which is adequate to orient a person if he wishes to do more intensive study. Although this book contains only 200 pages, it is a valuable addition and can be recommended to psychiatrists and all those students interested in the physical aspects of psychiatric therapy.

Vitamin and Mineral Content of Certain Foods as Affected by Home Preparation. By Elizabeth M. Hewston, Elsie H. Dawson, Lucy M. Alexander, and Elsa Orent-Keiles. Bureau of Human Nutrition and Home Economics, Agricultural Research Administration. United States Department of Agriculture, Miscellaneous Publication No. 628. Paper. Price, 30 cents. Pp. 76. Supt. of Doc., Government Printing Office, Washington 25, D. C., 1948.

Little accurate information is available about the retention of vitamins and minerals in the home preparation of foods. Food composition tables usually give figures for fresh, raw food and do not take into account the losses occurring during transportation, storage and household preparation. All persons interested in nutrition should welcome this informative publication which gives the results of a comprehensive investigation based on common methods in the home preparation of foods.

Twenty common foods were purchased on the open market. These were prepared in several different ways and the vitamin and mineral contents were determined. This bulletin gives the technics employed and the results of the various cooking methods. There is a comprehensive bibliography. It should merit the attention of all students of food and nutrition.

Osteophthisis Pelvis et Femorum: Zugleich ein Beitrag Zur Frage der spontanen Rückbildung maligner Tumoren. Von Dr. Gottfried Hartmann, Assistent des pathol. Anat. Institutes der Universität Wien, Wien. Wiener Beiträge zur Pathologie und pathologischen Anatomie, Band I. Boards. Price, $5. Pp. 183, with 19 illustrations. Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2; Distributors in U. S. A.: Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1947.

The author presents a case of extraordinarily extensive absorption of the skeleton involving complete disappearance of the pelvis, upper two thirds of the left femur and the head and neck of the right femur. The process began in the region of the left hip in a normal 16 year old girl, progressed rapidly for three years, and then gradually slowed down until it ceased about ten or twelve years after the onset. The patient had little pain or local symptoms, remained in relatively good health, getting about on crutches and even giving birth to 2 normal babies by cesarean section. She died at the age of 49 of a carcinoma of the stomach which had given local symptoms for only about four months.

At autopsy, a scirrhous carcinoma of the stomach was found with local peritoneal and retroperitoneal spread. Metastases were found in the resorbed areas of the pelvis and left femur and in the fourth and fifth lumbar vertebrae.

Among the possible causes for the local bone resorption, the author considers: (1) congenital malformation, (2) bone atrophy, (3) aseptic necrosis, (4) a new type of process, (5) parasites, (6) Hand-Schüller-Christian disease, (7) primary bone tumor (including cavernous hemangioma) and (8) metastatic bone tumor. He concludes that the latter best fits his case; namely, that a carcinoma of the stomach with osteolytic metastases occurred during adolescence of the patient with no local symptoms, that the osteolytic process finally ceased and the carcinoma lay "dormant" for over twenty years, becoming active just before the death of the patient with local symptoms from the primary tumor.

This is an interesting case, and it is regrettable that the author's conclusions must rest on speculation rather than sound evidence. If biopsy had been performed at the time the osteolytic process was active, the interpretation would be much more convincing. It is much more probable that the primary cause was not carcinoma and that metastases, if present, were late secondary complications.

A Rorschach Study on the Psychological Characteristics of Alcoholics. By Charlotte Buhler, Ph.D., Consulting Psychologist, Los Angeles County General Hospital, Los Angeles, and D. Welty Lefever, Ph.D., Professor of Education, University of Southern California, Los Angeles. Memoirs of the Section of Studies on Alcohol, Laboratory of Applied Physiology, Yale University, No. 6. Paper. Price, 75 cents. Pp. 64, with 14 illustrations. Distributed by Quarterly Journal of Studies on Alcohol, Box 2162 Yale Station, New Haven, Conn. Published for the Section of Studies *on Alcohol by Hillhouse Press, 432 Temple St.*, New Haven, Conn., 1948.

This monograph of 64 pages reports investigations by means of the Rorschach test in 100 alcoholic patients, 77 men and 23 women. The report limits itself to a description of a Rorschach sign list, which is published in full; to the application of this list in alcoholism; and to a description of a method of statistical analysis developed by the authors for studying the Rorschach test signs. The authors report findings in alcoholic addicts as compared with other clinical groups, and their conclusion as to the alcoholic addict's personality.

The monograph does not include a sample of the original Rorschach test records. A report on a Rorschach test investigation, without a sample of original test records, amounts to asking a reviewer to accept interpretations on faith, without the raw material that was interpreted. The authors do promise (page 13) that "detailed reports will be made elsewhere," since the present study is part of a larger one. Perhaps when these other reports are published, some Rorschach test records will be included. Until then the report is incomplete.

Atlas of Dental and Oral Pathology. Prepared at the Army Institute of Pathology from Material in The Registry of Dental and Oral Pathology of The American Dental Association. By Joseph L. Bernier, D.D.S., M.S., Lt. Col. Dental Corps U. S. Army, Chief of the Dental and Oral Pathology Section, Army Institute of Pathology, and J. E. Ash, M.D., Scientific Director of the American Registry of Pathology. Fourth edition of previous editions of James B. Mann, D.D.S., M.D., and Henry M. Goldman, D.D.S. Fabrikoid. Price, $7. Pp. 236, with 484 illustrations. American *Registry of Pathology*, National Research Council, *Army Institute of* Pathology, Washington 25, D. C., 1948.

Every member of the profession interested in this special field of pathology should own this atlas and refer to it frequently. The excellent physical format of writing and simplicity in style indicate that the authors are very familiar with their subject. They describe their subject in simple language. The description of the embryology and histology of the hard structures is by anatomic layers as the tooth is seen. The numerous photomicrographs are exceptionally clear.

The classification of odontogenic tumors is on an embryologic basis, whereas odontogenic cysts are discussed on a clinical basis. Soft tissue cysts are inaccurately included in this latter group. For the student, it might be well to classify these tumors uniformly.

The clinical descriptions of diseases involving the soft tissues of the mouth are not as accurate or as complete as the descriptions of the pathology of dental structure per se. Some of the clinical photographs would have greater teaching value if they were in colors.

This is probably the first book of this type to include a description of the effects of an atom bomb explosion on the oral tissues. This atlas is highly recommended.

Dr. Kirkbride and His Mental Hospital. By Earl D. Bond, M.D. Cloth. Price, $3.50. Pp. 163, with 7 illustrations. J. B. Lippincott Co., 227-231 S. Sixth St., Philadelphia 5, 1947.

Dr. Bond's book is not only an interesting, living profile of Dr. Thomas S. Kirkbride, the outstanding psychiatrist of his time, but is a notable addition to a rarely cultivated field, the history of psychiatry. Too often in this age we are so much intrigued with the important additions to a scientific discipline that we forget the labors and spirit of those pioneers who from few materials and with crude tools laid solid foundations without which the scientific superstructure could never have been erected. Such a pioneer and builder was Dr. Kirkbride. He not only realized that mental patients were human beings, people rather than psychoses, but constantly in his relation with patients he translated his beliefs and feelings into professional and personal behavior. Not routinely, but particularly and thoughtfully the medical, occupational and diversional needs of the patients under his care were served. In a sense he was the prophet of psychosomatics, for he understood so well that the so-called insane were unified and total in their functioning. Under Dr. Kirkbride, psychiatry achieved a high summit of humanitarianism. He bequeathed this rich legacy of care, understanding and treatment to the Pennsylvania Hospital, where it has been served conscientiously and faithfully by his successors, including Dr. Bond. Dr. Bond has brought to the writing of this book not only the accurate accumulation of valuable historical data, but the artistry of interesting and sympathetic description.

Handbook of Applied Pharmacology. Edited by Frederick Schroeder, M.D., F.A.C.P., and Arthur W. Grace, M.D., F.A.C.P., Formulary Committee of the Medical Board of The Long Island College Hospital, Brooklyn, N. Y. Fabrikoid. Price, $2. Pp. 133. The Long Island College Hospital, 340 Henry St., Brooklyn, N. Y., 1948.

This book represents essentially a compilation of the various therapeutic agents obtainable in the Long Island College Hospital. It has been prepared with the following objectives in view: "1. To acquaint the members of the Hospital Staff with the preparations carried in the Hospital Pharmacy for use in the In-and Out-Patient Departments; 2. To outline the dose, route of administration, size and nature of package of each material presented; 3. To indicate those conditions for which the preparations are employed." This purpose the authors have admirably fulfilled. This handbook should be of use to the house staff of the Long Island College Hospital as well as to the staffs of similar institutions, although in other institutions some of the therapeutic agents mentioned may not be obtainable.

Kinesiology Handbook: A Study Guide and Laboratory Manual. By M. Gladys Scott. Loose-Leaf. Paper. Price, $2. Pp. 148, with 25 illustrations. F. S. Crofts & Co., 101 Fifth Ave., New York 3, 1947.

As pointed out by Dr. C. H. McCloy in the introduction to this handbook, "the concepts of mechanics have usually been taught with no relationship to the movement of man." The author has overcome this difficulty by assembling special experiments and problems which do apply to man. This text is "designed as a workbook and study aid for students of kinesiology." It includes twenty-one lessons on various phases of kinesiology, and in each lesson there is an introduction, a list of references, a list of equipment required for the lesson, a description of the project and, finally, a list of questions elucidating the facts learned from the lesson.

Such subjects as motion in relation to structure of joints, action of the muscles of the various parts of the body, muscular tonus, muscular fatigue, leverage, inertia, relaxation, locomotor skills, development of muscular strength and of muscular tonus and measurement of strength of groups of muscles are discussed. Professors of anatomy in our medical schools might well advocate greater consideration of this subject in teaching of medical students, because modern physicians should be well grounded in kinesiology and functional anatomy.

This handbook is well organized and well planned and should prove a useful teaching aid, not only for students of physical education, physical therapy and occupational therapy but also for medical students.

Essentials of Fevers. By Gerald E. Breen, M.D., B.Ch., D.P.H., Tempy. Divisional Medical Officer, Hospitals Division, the London County Council, London. Second edition. Cloth. Price, $4.50. Pp. 351, with 40 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

Perhaps the chief criticism pertaining to this book is its title. If the term "contagious diseases" or "acute infectious diseases" had been used, it would undoubtedly have been considered in this country much more descriptive of the volume's contents. Beginning with "General Features of Infection" there are thirteen chapters, the final one relating to miscellaneous matters which include "Infectious Diseases and the Law." Most of the intervening titles represent primarily the various common contagious diseases, and a great deal of sound advice is presented in respect to diagnosis, treatment and related facts. It is apparent that the one who has written this book is not merely thoroughly familiar with his subject but that his observations are based on a broad personal experience. The plates in color are the accomplishments of the author as an artist. This is a practical book, concisely written, and printed with clear type on good paper. It should be of exceptional value to the medical student and appreciated in particular by the pediatrician.

Introduction to Human Physiology. By William D. Zoethout, Ph.D. Cloth. Price, $4. Pp. 421, with 142 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

This author has, in most respects, merely expanded the material presented in the accompanying laboratory guide, which is the outgrowth of many years of experience in teaching physiology to dental students. In that respect, it is on a soundly conservative basis. No one can take issue with the factual material presented. The textual material, however, is presented in a too elementary manner. Illustrations are good, many obviously prepared from original material. After each chapter there is a list of questions bearing on the chapter contents. The book should be excellent for high school students or college freshmen. Dental students should be able to digest a more adult diet.

The laboratory guide, in contrast, could be used even for medical students. Directions and illustrations are apt, concise and well composed and the material well selected, except, perhaps, some of the experiments on chemical reactions, which are rather elementary. Also experiments on human subjects are not numerous. This is always a serious defect in a physiologic laboratory.

Las arritmias en clínica (diagnóstico, pronóstico y tratamiento). Por el Doctor Antonio Battro, profesor adjunto de clínica médica de la Facultad de ciencias médicas de Buenos Aires. Paper. Pp. 511, with 200 illustrations. El Ateneo, Florida 340, Buenos Aires, 1948.

This work by the late Dr. Battro is an elaborately illustrated monograph concerning cardiac arrhythmias. It brings the subject up to date and includes work which the author and his collaborators have recently carried out, including observation on intracavity electrocardiography in man. It is divided into two parts. The first deals with the background material pertaining to arrhythmias, including the anatomy and physiology of the heart, the methods for graphic registration of the cardiac rhythm, as well as a more extensive section on the theory of the electrocardiogram and the characteristics of the normal electrocardiogram in the limb and chest leads. This latter section also discusses the so-called unipolar leads and the esophageal electrocardiogram. The second section considers the clinical aspects of the various arrhythmias. There is an extensive bibliography covering the important references in various languages dealing with this subject. The format is clear and the illustrations are beautifully reproduced and help to document the manuscript. This volume should be of interest to the cardiologist.

Diseases of the Heart and Circulation. By Albert A. Fitzgerald Peel, M.A., D.M., F.R.F.P.S., Professor of Medicine, Anderson College of Medicine, Glasgow. Oxford Medical Publications. Cloth. Price, $9.75. Pp. 398, with 61 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Square, London, E. C. 4, 1947.

The author presents the conventional, modern concepts of heart and vascular disease. To accomplish this objective in 400 pages, he has had to limit many subjects to brief paragraphs, but there are few omissions. The roentgen illustrations are excellent and the electrocardiographic reproductions are fair to good. The bibliography is limited. The American Heart Association Classification of Heart Disease has been adopted by the author. In his discussion of the treatment of subacute bacterial endocarditis, it becomes clear that the use of penicillin in the British Isles is more limited than in the United States, possibly due to limited supplies.

Recent Advances in Endocrinology. By A. T. Cameron, C.M.G., M.A., D.Sc., Professor of Biochemistry, Faculty of Medicine, University of Manitoba, Winnipeg, Canada. Sixth edition. Fabrikoid. Price, $6. Pp. 443, with 74 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1947.

Considering its concentrated form, this book gives an excellent presentation of the essentials of endocrinology for the reader who does not want a mass of detail and yet wishes competent scientific treatment of the subject. Recent advances in our knowledge are stressed. The book brings up to date the experimental work pertaining to function of the endocrine glands and also deals with the latest discoveries and methods of treatment of their diseases.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

THEOBROMINE IN ANGINA

To the Editor:—Please discuss the present use of theobromine preparations, especially of "theocalcin," in cardiac therapy. What is the physiologic action with reference to the arterial system in general and the coronary arteries in particular? What other drugs are of use in anginal conditions due to a narrowing of the coronary arteries?

E. W. Hunter, M.D., Greenwood, Miss.

Answer.—In animal experiments, theobromine and theophylline possess a dilator effect on the smooth muscle of the arteries, thus lowering slightly the normal blood pressure. The coronary arteries dilate, and a greater flow through these arteries is obtained in both anesthetized and nonanesthetized dogs (Essex and others: *Amer. Heart J.* **19**:554, 1940). Furthermore, xanthine derivatives increase slightly the contractility of the heart muscle without influencing its rate of contraction. The effect on contraction is more strikingly obtained in the weakened or damaged heart of the dog (Flaum, E., and Rössler, R.: *Klin. Wchnschr.* **12**:1489, 1933). Treatment with aminophylline has been claimed to decrease the size of infarcts following surgical occlusion of a branch of the coronary arteries in dogs (Fowler, W. M.; Hurevitz, H. M., and Smith, F. M.: *Arch. Int. Med.* **56**:1242, 1935). More recently Mokotoff and Katz (*Am. Heart J.* **30**:215, 1945) found that aminophylline (and, to a greater extent, papaverine) significantly reduced the size of experimental infarcts in dogs and also increased the size and number of collateral channels in the infarcted heart. Similar experiments by Gold and others (*Am. Heart J.* **14**:284, 1937) on cats, however, failed to demonstrate any influence of aminophylline on the infarcted area and on the survival time of the animals.

In the management of the patient suffering from the anginal syndrome the use of xanthine derivatives introduced by Askanazy in 1895 has become a matter of controversy, since Evans and Hoyle (*Quart. J. Med.* **2**:311, 1933) found that the treatment with these preparations did not prevent the occurrence of anginal pain to a greater extent than the administration of placebos. The results of their studies based on the statements of the patients were confirmed by some investigators in this country, but contradicted by others who obtained a salutary effect from these drugs as compared to placebos. On the other hand, Brown and Riseman (J. A. M. A. **109**:256, 1937), using an exercise tolerance test as an objective index, reported improvements in the performance of these tests in 80 per cent of their patients under treatment with theobromine with sodium acetate or theophylline with sodium acetate. A 50 per cent or greater improvement accompanied by decrease in number and diminution in severity of the anginal attacks was obtained in about 25 per cent of their patients. The effect of xanthine derivatives in cardiac patients was further studied by Williams and associates (*Am. Heart J.* **22**:252, 1941) by measuring the deviations of the RS-T waves induced by anoxia. They reported a marked diminution of the sum of the RS-T deviations when the patients were maintained on theobromine or theophylline.

Theobromine with sodium acetate, theobromine with calcium salicylate, aminophylline, theophylline with sodium acetate and theobromine with calcium salicylate are reported to be superior to other xanthine derivatives. Tolerance to all preparations is limited by the degree of gastric distress caused by larger doses, and also, more frequently with theophylline, by insomnia. Maximum tolerated doses usually do not exceed 0.5 Gm. of theobromine with sodium acetate four times daily (equivalent to 1.2 Gm. of theobromine per day) or 0.2 Gm. of aminophylline four times daily (equivalent to 0.6 Gm. of theophylline). No evidence is available to show that theobromine with calcium salicylate ("theocalcin" N. N. R.) is more effective than theobromine with sodium acetate. It is somewhat less soluble than the latter and is supposed to cause less gastric distress.

Admittedly, the evidence for the efficacy of xanthine derivatives is still inconclusive. The lack of other, more effective drug therapy seems largely responsible for their continued use in the treatment of the anginal syndrome. According to Elek and Katz (J. A. M. A. **120**:434, 1942) papaverine hydrochloride given orally in doses of 0.1 Gm. four times daily promises to be more effective than aminophylline.

CAVERNOUS SINUS THROMBOSIS

To the Editor:—Discuss the use of heparin and "dicumarol" in treatment of cavernous or sigmoid sinus thrombosis under the following heads: (a) reasons for using these medications; (b) when should one use heparin with or without Pitkin's menstruum? (c) When should one use "dicumarol?" (d) What laboratory tests are necessary for control of each drug? (e) When should one discontinue use of these drugs? (f) What is the mechanism of action of heparin and "dicumarol?"

James R. Bishop, M.D., Salisbury, Md.

Answer.—While the total experience available to date is relatively limited, the use of heparin and "dicumarol" either together or separately in the treatment of cavernous or sigmoid sinus thrombosis seems justified. This is established on the basis of the large experience in this country and in Sweden which has resulted in diminishing both the death and complication rate in patients with thrombophlebitis. Substantiation of the favorable effect on thromboembolic diseases has now been established by the Committee for the Evaluation of Anticoagulants in the Treatment of Coronary Thrombosis with Myocardial Infarction. While a few patients have been so treated, further work needs to be done in the specific field of cavernous sigmoid sinus thrombosis, but the evidence appears strong that favorable results may be expected. If the patient were acutely ill, heparin would be indicated during the first three or four days until the effect of "dicumarol" given on the beginning of the first day would be established.

The use of Pitkin's menstruum with heparin would be an optional alternative to the combined use of heparin and "dicumarol." It should be pointed out, however, that the present preparations are frequently painful and control of the action of heparin is sometimes not well regulated. "Dicumarol" may be utilized in any patient with cavernous or sigmoid sinus thrombosis unless there are contraindications such as hemorrhagic tendencies. For the control of heparin the Lee-White clotting time test is still the most satisfactory, although it is relatively a crude test. The clotting time should be kept on an average of three times the normal clotting time if continuous infusions are used. If the Swedish or intermittent technic is used, the clotting time should return to approximately 10 to 15 minutes at the end of a three and one-half hour interval after an infection of 50 or 75 mg. of heparin. The Quick test or the Link-Shapiro modification should be used for the determination of the prothrombin time for the control of "dicumarol." If desired, the times may be translated in percentage of activity, provided that this is done by the logarithmic curve method which has been described frequently.

In general, it is wise to continue the use of these drugs for twenty-one to twenty-eight days after the last thromboembolic complication. The action of heparin is probably a neutralization of the action of thromboplastin which is an essential factor in the initial phase of the clotting process. The action of "dicumarol" is believed to be based on the prevention of the production of prothrombin by the liver. This information is taken from publications by E. V. Allen and Barker of the Mayo Clinic; E. Jorpes and his co-workers in Sweden; Wright and his co-workers, and K. P. Link and his co-workers.

TRAUMA IN OBSTETRICS

To the Editor:—What role does trauma play in premature separation of the placenta? I have been unable to get any specific, clearcut opinion on this subject from the literature.

M.D., Connecticut.

Answer.—Undoubtedly the role of trauma in the development of premature separation of the placenta has been overemphasized. The older literature particularly stressed that trauma was an important factor in abruptio placentae. Rigby in 1776 considered trauma to be the most important cause of this condition. De Lee and Greenhill (Principles and Practice of Obstetrics, ed. 9, Philadelphia, W. B. Saunders Company, 1947) quote Rigby as saying "separation of the placenta must be owing to some accidental circumstance, to violence done to the uterus by blows or falls, to some peculiar laxity of the uterine vessels from badness of habit, or fever, or to some influence of the passions of the mind suddenly excited, such as fear, anger, etc." The term "accidental hemorrhage" is still used, especially by British authors, to designate the premature separation of the normally implanted placenta. In Holmes's collection of 200 cases of abruptio placentae from the literature (*Am. J. Obst.* **44**:753 [Dec.] 1901) accident was given as the cause in 67 or 33.5 per cent, but in Davis and McGee's series of 164 cases observed at the Chicago Lying-In Hospital, only 3, or 1.8 per cent, were associated with trauma (*Surg., Gynec. & Obst.* **53**:768 [Dec.] 1931).

Whereas external trauma and violence are infrequent causes of premature separation of the placenta, internal trauma is not rarely the cause. During labor several accidents may cause detachment of the placenta, as sudden emptying of a large polyhydramnios, the loosening of the placenta which sometimes follows the delivery of the first twin, manual manipulation during version, use of bags, bougies, gauze and, finally, traction exerted on the placenta by a cord that is actually or relatively too short.

KAHN "VERIFICATION TEST"

To the Editor:—Could you explain the Kahn verification test and offer suggestions for the following patient? A white male farmer 54 years old was seen in September 1946 complaining of severe steady aching pain in both feet only at night. He had been treated for nervous indigestion for years but had not had other serious illnesses. Physical examination did not reveal any abnormality except for pupils that were slightly irregular, were sluggish to light but reacted to accommodation, a systolic aortic murmur, only suggestive Romberg sign and absent patellar reflex. Pain was not felt on either side when the achilles tendons were pinched. The fundi prostate and urine were normal; hemoglobin was 100 per cent; the hematocrit reading 45 per cent. He complained of some difficulty in seeing in the dark which has cleared some on antisyphilitic therapy. The serologic reactions were as follows: Aug. 31, 1946, Kahn positive; September 16, Kahn positive (20 Kahn units, Springfield Laboratory); September 16, Kahn positive (20 Kahn units, Chicago State Laboratory); November 22, positive (4 units); Feb. 6, 1947, positive (10 units); May 31, positive (4 units); August 28, positive (4 units); October 20, positive (2 units); October 21, positive (3 units, Chicago State Laboratory); Jan. 5, 1948, positive (2 units) and May 12, positive (3 units, Chicago State Laboratory); reaction to Kahn verification test, general biologic (false positive). He has had alternating courses of bismuth and dichlorophenarsine hydrochloride until the present. Is further treatment indicated and did the patient have syphilis in the first place? Is a spinal fluid examination necessary for the diagnosis?

Clifford W. Atherton, M.D., Fairview, Ill.

ANSWER.—The question was referred to an eminent syphilologist who says that the Kahn "verification test" is hard to explain since Dr. Kahn changes the rules frequently. As one procedure fails to work, he adopts another. Now he is probably using a combination of four different technics based on a "differential temperature phenomenon," a "triple quantitative technic," a "salt dispersibility technic" and "method B." Since none of these alone or in combination produced the desired result, it is possible that new maneuvers have been added which have not yet been widely published. It is beyond the scope of this reply to explain the reasoning behind the Kahn "verification" test (or tests). The technical details are complicated and an understanding of them is not necessary to interpretation of the test by the average practitioner.

There are three Kahn tests in common use in Kahn's laboratory, and two of these have been widely adopted by other serologic laboratories. These are as follows:

1. The standard Kahn test. This is a flocculation test which differs only in minor technical details from other flocculation tests such as those devised by Mazzini, Hinton, Eagle, and others, and in the hands of a competent technician it gives reliable results, whether on a quantitative or a qualitative basis.

2. The Kahn "presumptive" test. The naming of this test would indicate that its results permitted the physician to "presume" that a patient did or did not have syphilis. This is an erroneous assumption. The "presumptive" test requires the use of a supersensitive antigen, so sensitive that in the hands of the average technician false positive results are secured in a substantial proportion of nonsyphilitic persons.

3. The Kahn "verification" test. The naming of this test would indicate that it verified something; namely, that if a "syphilitic type" reaction is reported, the patient has syphilis; whereas if a "general biologic type of reaction" is reported, the patient does not have syphilis, but does have a biologic false positive serologic reaction. Actually the Kahn "verification" test does not verify anything. It has been shown by investigators other than Kahn that the results of this test, whether "syphilitic type" or "general biologic type," are closely related to the serologic titer of the serum in question. Serums positive in low quantitative titer only, whether from patients with syphilis or from those with nonsyphilitic diseases causing biologic false positive reactions, usually give the "biologic type of reaction" with this Kahn test. Conversely, serums of high quantitative titer, regardless of their source, usually give reactions of the "syphilitic type."

The Kahn "verification" test is one of a number of procedures, the latest of which is the Neurath euglobulin-inhibitor test, designed to differentiate positive serologic reactions due to syphilis from biologic false positive reactions caused by other conditions or occurring in some normal persons. No one of these procedures can be regarded as wholly satisfactory or as furnishing absolute laboratory differentiation of this difficult diagnostic problem.

4. The results of the Kahn "verification test" of the patient described in this inquiry may be totally disregarded. A patient with irregular pupils, reacting sluggishly to light but normally on accommodation, absent patellar reflexes, loss of deep pain sense in the achilles tendons and difficulty in dark adaptation almost certainly has tabes dorsalis, regardless of the outcome of any blood serologic test, whether Kahn standard, presumptive, or "verification," or any other technic. In addition, it is at least suggested that the patient also has cardiovascular syphilis.

The patient in question should at once have a detailed examination of his spinal fluid, including cell count, quantitative protein estimation, quantitatively titered complement fixation (not flocculation) test and colloidal test. In addition, he should certainly have neuropsychiatric and cardiologic or competent syphilologic consultation.

If he has tabes dorsalis with or without cardiovascular syphilis, treatment with bismuth and arsenic compounds should be abandoned in favor of penicillin. It may be desirable to combine penicillin with fever therapy by means of induced tertian malaria. Whether this is the case depends on the patient's general physical condition, his cardiac and neuropsychiatric status and the results of his spinal fluid examination.

5. The spinal fluid examination is necessary for diagnosis in every patient with syphilis, and the physician who attempts to treat syphilis without examination of the spinal fluid is proceeding in the dark.

6. It is suggested also that the inquirer consult modern texts on syphilis and its treatment, such as Stokes, Beerman and Ingraham, "Modern Clinical Syphilology (third edition, Philadelphia, W. B. Saunders Company, 1944), or Moore, J. E., "The Modern Treatment of Syphilis" (second edition, Springfield, Ill., Charles C Thomas, Publisher, 1943) and "Penicillin in Syphilis" (Springfield, Ill., Charles C Thomas, Publisher, 1946).

CHRONIC HEPATITIS

To the Editor:—A young man, age 31, served with UNNRA in Germany. In November 1946 while there he became ill and was given a diagnosis of acute hepatitis. One year later he complained of tiredness, lethargy, white stools, gaseous distention of the bowel and diarrhea. The condition had been present for ten days and was progressive. He stated that he had had several episodes similar to the present attack in the year preceding. An icteric index of his blood was 19.5. I made a diagnosis of chronic hepatitis with acute exacerbation and put him on "meonine" (DL-gamma-methylthiol-alpha-aminobutyric acid) twelve tablets daily, and a high protein diet. He recovered and the icteric index was 7.1 ten days later. His icteric index has run from 7.1 to 11.8 ever since. There have been episodes of white stools and lethargy at intervals of several weeks, in spite of "meonine" therapy, B complex and high protein diet. Please comment on diagnosis, therapy and prognosis.

Albert Irving Clark, M.D., Shreveport, La.

ANSWER.—The diagnosis of chronic hepatitis during an acute exacerbation is probable but hardly proved by the data presented. The commonest symptoms of such a condition are dull aching pain in the right upper quadrant and marked intolerance to fatty foods; the commonest physical sign is hepatomegaly, and the most definite laboratory findings are (1) elevation of the indirect reaction for serum bilirubin, (2) retention of sulfobromophthalein sodium, (3) increased thymol turbidity and (4) increases in the value for serum globulin and in the sedimentation rate of erythrocytes. Since the only laboratory finding mentioned in the case report is an increased icterus index, further studies of hepatic function should be undertaken before the diagnosis is considered as established. Constitutional hepatic dysfunction with hyperbilirubinemia comes to mind as a possible condition to be excluded, not to mention one of the hemolytic varieties of icterus.

Active hepatitis has been demonstrated by needle biopsy of the liver months after an acute infectious hepatitis has subsided; in some cases the only abnormalities noted have been increases in the level of urinary urobilinogen and the urinary content of coproporphyrin. The exact pathologic and physiologic residues of the acute disease are not as yet fully catalogued, and only long observation of those who have had the disease and presumably have recovered and of patients such as the one described here will establish the diagnosis of chronic hepatitis on a secure footing.

The prognosis for chronic hepatitis is uncertain; in some cases the disease seems to progress, and either chronic atrophy of the liver or what has been called "cholangiolitic cirrhosis" develops. Some patients seem to recover, while others have persistent complaints, similar to those of the patient under discussion, for indefinite periods, without ever presenting much in the way of objective evidence of disease.

Treatment of chronic hepatitis is unsatisfactory; restriction of activities, an adequate diet with a high protein content, lipotropic agents such as choline and methionine, liver extract by the intravenous route and high level vitamin therapy have all been recommended, but it is not clear that much improvement has taken place with any or all of these therapeutic agents.

SCLERODERMA

To the Editor:—In a woman patient affected by scleroderma the symptoms were scarcely improved by "etamon" (tetraethyl ammonium chloride) "priscol" (abenzylimidazoline) vitamin D and thyroid. I received news from the United States that the acid-fast sclerobacillus of Wuerthele-Caspe had been discovered and considered as the cause of this sickness. Therefore "promin" (sodium p,-p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate) and streptomycin are indicated. Is there evidence of recovery with these drugs in this disease that has been until now considered a metabolic disease? Does this therapy deserve a trial?

Roberto Pietra, M.D., Torino, Italy.

Answer.—Doubtless reference is made to the following report—Wuerthele-Caspe, V.; Brodkin, E., and Mermod, C.: Etiology of Scleroderma, A Preliminary Clinical Report, *J. M. Soc. New Jersey* **44**:256 (July) 1947. This is a preliminary report on a probable bacterial cause of scleroderma and on its treatment with an antibacterial agent. On the supposition that the organism is a mycobacterium as in leprosy and tuberculosis it was reasoned that the organism should be found in nasal ulcers, subcutaneous tissue.

Six cases of scleroderma were reported. A mycobacterium was recovered from these patients either from nasal ulcers, sputum, subcutaneous tissue or by blood culture. The organism was described as a short, thick, acid-fast rod. Smears were prepared by the Ziehl-Neelsen method. Blood was cultured on Dubo's medium and showed after two weeks' growth a pure culture of short, thick, acid-fast rods.

The ulcerations of the fingers of 1 patient with sclerodactylia were treated with local applications of 5 per cent sodium p,p'-diaminodiphenyl sulfone-N,N'-didextrose sulfonate ("promin") in jelly made of tragacanth. It was reported that the ulcerations healed with considerable improvement in the flexibility of the hands. Other patients were treated with "promin" administered intravenously or orally.

Before judgment can be passed of the bacterial cause of scleroderma and treatment with "promin," further study and confirmation are required.

RETINAL HEMORRHAGE

To the Editor:—Is it advisable to administer rutin prophylactically to prevent recurrence of hemorrhagic retinitis? A patient, now 57, diabetic, had retinitis thirteen years ago, and another attack two years later which was so severe that the ophthalmologist feared that the sight of one eye would be permanently lost. However, he recovered to the extent that he can read newspaper type for a short while until the effort tires him. He has not used insulin for eight years and has a constant blood sugar level of 127 mg. He fears another attack of retinitis.

M.D., New York.

Answer.—From the description of the patient's clinical course, it would seem that the prognosis is none too good inasmuch as there have already been two attacks of retinitis. The vascular state of the retinal vessels is probably none too good and a degenerative retinopathy probably exists as well as some vascular sclerosis. Rutin exerts a beneficial effect in cases of increased capillary fragility. In this case, I know of no definite manner in which you can assure your patient that future attacks can be prevented. On the other hand, no legitimate reason would seem to exist to prevent you from using rutin prophylactically in the hope that it may prevent another attack, or if it does not prevent another attack, it may at least have the effect of diminishing the total effect of an increased capillary fragility.

PES PLANUS

To the Editor:—I have a severe grade of pes planus. For several years I have tried to correct my deformity with exercises, and have worn arch supports at various time without avail. Is manipulation of benefit?

M.D., Georgia.

Answer.—Flatfoot or pes valgoplanus in an adult can be corrected. Only if the foot is fixed or rigid, which means that the position cannot be changed voluntarily, would a manipulation with the patient under anesthesia be required. With a definite muscle spasm and the foot held in the everted position it may require rest with hot packs, or occasionally local or general anesthesia, to get the muscles relaxed. Then the foot can be brought into normal position.

Usually the pes valgoplanus is present with weight bearing and the valgus position of the heel can be corrected and the anterior part of the foot brought back into normal position by conservative means. This is best accomplished by having a pliable shoe with the heel raised on the inner side, and a comma-shaped bar which is higher on the lateral side than on the medial side, attached to the sole of the shoe. Thus the heel is brought into varus and the head of the first metatarsal bone is brought down plantarward. This reestablishes the longitudinal arch as well as the anterior arch. The normal position is retained by the corrective shoe, but this in itself is insufficient. Normal walking must then be practiced in the shoes. This means heel and toe walking. The normal use of the foot in the corrected position will gradually reestablish the strength of the muscles. The symptoms will thus be relieved and the appearance of the foot will improve. It must be emphasized that the use of the corrective shoe should be gradual, starting with five minute periods ten times a day and increasing the walking periods gradually until the shoes can be worn a half day and finally a full day.

HISTAMINE IN MIGRAINE

To the Editor:—I contemplate treating a patient with severe migraine with intravenous administration of histamine. She has not responded to other therapy. What is the efficacy of this method of treatment?

LaMar J. Hankamp, M.D., Delton, Mich.

Answer.—The results of intravenous histamine therapy, as now used for migraine, histaminic cephalgia and Ménière's disease, are in general excellent. In a large series of true migraines, carefully screened to eliminate other sources of headache or pain, authors report almost 80 per cent of either total and permanent relief up to five years, or a degree of improvement in frequency, severity and duration of attacks such that they constitute only a minor annoyance rather than disability. To the present time there is no reliable basis on which to determine whether a particular person will respond satisfactorily to intravenous histamine therapy, or will belong to the approximately 20 per cent in which this treatment fails.

Others report satisfactory results particularly after abandoning the technic of frequent single injections increasing as tolerated, in favor of prolonged exposure (three to ten hours) to intravenously administered histamine at the maximum tolerated rate of injection. Before undertaking the procedure, one should be thoroughly competent to recognize, prevent and treat the numerous and serious reactions which may frequently accompany this procedure, in particular increased gastric acidity with occasional aggravation or reactivation of peptic ulcer—or rarely gastric hemorrhage from unsuspected ulcer—severe typical headache, rapid fall of blood pressure with potential shock, urticaria, asthma or other manifestations of anaphylaxis.

BIURET REACTION

To the Editor:—We have attempted to use the biuret method in the colorimetric determination of total proteins, albumin and globulin with variable results. I would appreciate learning whether there are any other good methods applicable to a spectrophotometer.

M.D., Utah.

Answer.—The two most common methods for the quantitative spectrophotometric determination of total proteins, albumin and globulin are the biuret reaction, which depends on color development with copper sulfate, and the Folin phenol method, which involves the use of a tungstate-molybdate reagent. Robinson and Hogden (*J. Biol. Chem.* **135**:707-731 [1940]) consider the biuret reaction to have certain advantages over the Folin phenol procedure, particularly in that the color intensities developed in the latter method are different for albumin and globulin. An excellent review and bibliography on the biuret method occurs in "Advances in Protein Chemistry," volume III, pages 149 to 150. Greenberg and Mirolubova describe in detail a modified procedure using the Folin phenol reagent in the *Journal of Laboratory and Clinical Medicine* (**21**:431 [1936]). The procedure with pertinent remarks is found in "Outline of the Amino Acids and Proteins," by Sahyun, pages 146 to 149.

TATTOO

To the Editor:—What solutions are used for "tattooing in reverse?"

Arthur J. Ring, M.D., Lynn, Mass.

Answer.—Physicians remove tattoos by tattooing or by plastic surgery. The most widely used method is thoroughly to tattoo 40 per cent tannic acid into the lesion with needles, after which 50 per cent silver nitrate is applied to the area until a hard adherent crust is formed. The area is bandaged and the crust is allowed to come off naturally. It usually takes two treatments, and, as a rule, little scarring results.

CORRELATION OF GASTROENTEROLOGY AND SURGERY

Chairman's Address

SARA M. JORDAN, M.D.
Boston

Harmony and cooperation are basic cornerstones in all fields of human endeavor the purposes of which are the accomplishment of good. This statement is as significant as it is axiomatic. It needs neither emphasis nor elaboration in the world of today, where its antithesis, the effect of disharmony and lack of cooperation, is so clearly demonstrated and, by contrast, so revealing.

Medicine is *par excellence* a field in which the accomplishment of good is the prime and ultimate purpose. For its attainment, harmonious cooperation is as essential as vocational aptitude and training. The inevitable specialization which has resulted from the broadening and development of medical science during the past few decades has had as a natural consequence the development of an absorbing interest in each specialty, which becomes at times so intensive as to be exclusive and narrowing. Pride in the scope and immediate effect of such intensive effort within a special field may become so great that there is failure to recognize unsuccessful end results or need for ancillary treatment.

The fields of gastroenterology and surgery are striking examples of accomplishment within their own limits, but they also exemplify to a high degree the demanding need for harmonious correlation. The successful diagnosis and treatment of diseases of the digestive tract depend on the knowledge and experience of both gastroenterologist and surgeon. Neither has an inclusive monopoly on this field, and best results are obtained only if both work with tolerance and cooperation. Gastroenterology is, to be sure, concerned chiefly with the diagnosis, medical management and follow-up observations, in both the nonsurgical and surgical groups, but the operative procedures and observations, while, by nature, of strictly surgical interest, concern the gastroenterologist as well. The timing in the use of such operations is of the greatest interest to gastroenterologists. Conversely, surgery, while occupied chiefly with the development of correct and effective therapeutic surgical procedures, is naturally deeply concerned that these procedures be used on the right patient for the right reason and must, therefore, have an intense interest in all that involves gastroenterologic diagnosis and treatment. Both gastroenterology and surgery find their justification in end results and modify their procedures either on the radical or the conservative side, according to the final outcome of their respective treatments.

The ideal relationship of gastroenterologists and surgeons is, therefore, one in which there can be reasoned discussion of procedures, cases and results without the barriers of prejudice, suspicion or patronizing attitude of one for the other. A natural desire to avoid unnecessary operation is as much a part of good surgery as it is of good gastroenterology, whereas the call for aid from surgical intervention must come from the gastroenterologist as soon as he is convinced that it is necessary. The observations in both diagnosis and end results are of equal concern to gastroenterologist and surgeon. Each has an opportunity to give of his experience to the other, and in a harmonious relationship only the greatest good for the patient can result.

The diagnosis and treatment of all digestive diseases concerns both gastroenterologist and surgeon, but the conditions in which cooperative observations and treatment are of highest importance are in the differentiation of structural and functional disease, in the diagnosis of cancer of the digestive tract and in the diagnosis and treatment of peptic ulcer, gallbladder disease and inflammatory and ulcerative diseases of small and large intestines.

Differentiation of structural and functional disease is in all parts of the body not without its pitfalls, but the digestive tract, easily accessible as it is to abuse and irritation, harbors, perhaps to a greater degree than any other part of the body, peculiar perplexities for the diagnostician. In the past, many normal gallbladders and appendixes have been removed and surgeons perhaps temporarily comforted by pathologic reports of chronic cholecystitis and appendicitis, only to have unhappy patients return after a few months with recurrence of the preoperative symptoms. To be sure, careful exploration had shown no evidence of other structural disease, but there had also all too often been no careful preoperative exploration by a gastroenterologist. When the surgeon failed on exploration to find other organic disease and to provide relief by the removal of appendix or gallbladder, patients were classed as psychoneurotic or hypochondriac, whereas if they had been surveyed preoperatively by both gastroenterologist and surgeon, there would have been neither operation nor disappointed patients.

Abdominal symptoms, while at times so distinctive and typical that no survey or period of observation is necessary to make a diagnosis, often require the most scrutinizing survey, not only to determine the chief and underlying cause of symptoms but also to detect other secondary conditions which contribute to the symptomatic picture and which, if undetected,

Read before the Section on Gastroenterology and Proctology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

will continue to cause symptoms after the chief cause has been treated. For example, no disease of the digestive tract, whether organic or functional, when associated with gallstones can be satisfactorily treated until the gallbladder has been removed. Conversely, no cholecystectomy will produce entirely satisfactory results if an associated irritable colon and hypermotility of the small intestine is not treated immediately postoperatively. In the interest of time saving and effectiveness of treatment, therefore, a complete survey is indispensable in all patients who have abdominal symptoms. Errors in diagnosis and treatment are too often due to failure to carry out a complete examination previous to treatment.

Functional disorders which are present in conjunction with organic disease and organic disease lurking under cover of obvious functional disorders are too often found in a complete diagnostic survey to allow of exclusively concentrated attention on one typical group of symptoms. In this regard, two points are worthy of special mention. Reference was made previously to the frequent occurrence of irritability of the colon and hypermotility of the small intestine in conjunction with gallstones. A policy proved especially useful is that of classifying patients with gallstones into two groups: first, those who have chronic indigestion, characterized by gas distress and distention, sometimes with nausea and vomiting and with or without typical gallbladder colic, and, second, those who have typical gallbladder colic attacks, but no chronic indigestion between attacks. The first group has inevitably a functional digestive disorder which is not corrected by cholecystectomy alone, but which requires both cholecystectomy and postoperative medical treatment of the digestive disorder. The second group recovers completely from cholecystectomy alone.

A second point of relevant interest concerns the diagnosis of gallbladder disease, in the presence of both acute peptic ulcer and severe functional disorders in which there is pronounced pylorospasm, probably with associated spasm in the ampulla of Vater and cystic duct. In such cases the reaction to the Graham-Cole test may appear to be positive when the test is made in the presence of these acute conditions, but a week or ten days after the acute condition has been relieved by medical management a normal response to the Graham-Cole test is obtained, proving that the gallbladder had a functional but not a structural disorder.

Diagnostic problems with peptic ulcer are much commoner than might be expected from the fact that the history of uncomplicated ulcer has such a standard pattern. The occurrence of concomitant disease, as well as of complications of the disease itself, changes the clinical picture, sometimes to a decided degree. Joint observation and experience of both gastroenterologist and surgeon are usually required for the best therapeutic outcome.

Indications for surgical intervention in ulcer vary with the individual surgeon and gastroenterologist, but wherever there is harmonious cooperation the appraisal of good and bad end results of both medical and surgical treatment has resulted in the tempering—by humility—of initial enthusiasm for one or the other treatment and in the eager search for help by one from the other. The surgeon is willing to have only the intractable duodenal or jejunal ulcer or the gastric ulcer suspected of malignant disease referred to his care, and the gastroenterologist eagerly seeks his aid when this becomes necessary.

The question of intractability is indeed a relative one. The tendency of this disease to recur after any form of treatment makes it necessary that the newer radical procedures be used only when indicated by absolute failure of conservative measures. Particularly, is it important that conservative measures be given a truly adequate trial, and without careful investigation into the adequacy of such measures an immature appraisal often leads to unnecessary operation. On the other hand, penetration of a truly recalcitrant ulcer into the essentially important region of the common duct with its plastering effect on that vital area makes the inevitable surgical procedure extremely difficult and sometimes impossible of ideal execution. Ulcers of the second portion of the duodenum should, therefore, probably have an earlier diagnosis of intractability than those in areas where less vital structures may be involved. The criterion of intractability is, therefore, dependent on careful analysis of previous treatment and the type and location of the ulcer. Much has been said in discussions of peptic ulcer about the intractable patient versus the intractable ulcer. It cannot be too often emphasized that unless such a patient is so impressed by the gravity of a surgical procedure that he will postoperatively become a tractable patient his intractability will operate with as much disadvantage to him postoperatively as it did during his medical regimen. In other words, surgical intervention alone has proved to be no panacea for the intractable patient.

Postoperative care in ulcer often challenges the best efforts of the gastroenterologist and surgeon. Patients about to have gastric resection should be freed from any preoperative illusion that resection gives them emancipation from all medical restrictions. The incidence of jejunal ulcer after resection is sufficiently high to make it necessary that medical care be continued postoperatively and establishes the fact that the operation is an added therapeutic procedure, but not a substitution.

Postoperative complications after resection for ulcer often tax the clinical judgment of both gastroenterologist and surgeon. As an illustration of this fact, there is the patient who has had gastric resection and who returns with new complaints of abdominal distress. The question arises: has this patient a jejunal ulcer, a postoperative dumping syndrome, a functional disorder of the colon or a new organic lesion unrelated to his previous ulcer and resection? Meticulous observation and investigation may be required to differentiate. Pain to the left of the umbilicus, tenderness with fluoroscopic examination over the stoma and a residual fleck of barium sulfate at the site of tenderness indicate a jejunal ulcer, and this or any other new organic lesion should be found with careful study. The dumping syndrome or a functional disorder of the colon is suspected if neither jejunal ulcer nor new organic lesion is found, and the diagnostic study, especially the history and roentgenologic observations, indicates which of these conditions exists. Not infrequently, a functional colonic disorder is induced by ulcer therapy, particularly if the silicates and magnesium have been used.

Obstruction is a complication of ulcer which, while often thought to be definitely an indication for surgical intervention, is equally often observed to be a transient condition due to edema and inflammation and not to cicatricial stenosis. A period of observation with alternate feeding and drainage, known at the Lahey Clinic as the Wilkinson drainage method, because first devised by Dr. S. Allen Wilkinson, is usually an effective method of differentiation between transient and permanent obstruction and helps in the assignment of such cases to medical or surgical treatment.

Hemorrhage in peptic ulcer is a complication which, as time and ulcer experience go on, often has been found to test the clinical acumen and judgment of both gastroenterologist and surgeon. The diagnosis of ulcer in gastrointestinal bleeding is often difficult to establish, even with surgical exploration. One point of interest worth noting is that some of these apparently obscure bleeding ulcers are located in the second portion of the duodenum, and their presence is indicated roentgenologically by a narrowing of that area with a paradoxic dilatation distal to the ulcer, a sign first called to our attention at the Lahey Clinic by Dr. Wilkinson, of our staff.

Ulcer bleeders have a deplorable tendency to bleed after all forms of treatment, medical and surgical. Patients with such conditions, with histories of multiple hemorrhages, must receive special and intensive postoperative treatment after resection, for statistics are gradually accumulating which indicate a considerable percentage of hemorrhage following even very high resections. The whole problem of ulcer hemorrhage requires cooperative study by surgeon and gastroenterologist.

Newer surgical and medical procedures for ulcer should have the consideration and appraisal of both gastroenterologist and surgeon. For example, the two newer methods of treatment—the surgical procedure of vagotomy and the hormonal approach to treatment with enterogastrone and other hormonal extracts—require analytic appraisal of results before general adoption is recommended. The American Gastroenterological Association, through its Committee for the Study of Peptic Ulcer, is at present engaged in such an appraisal on a national level and intends to obtain a final opinion of their value as indicated by end results.

Such end results can, of course, be truly appraised only with time, the determining factor in all ulcer statistics, but already enough time has elapsed in the case of vagotomy results to indicate the trend of results and the presence or absence of untoward side effects. The cooperation of surgeon and gastroenterologist is essential to effect such an appraisal, the result of which will be either the promotion or the condemnation of this procedure. While less important from the point of view of life and safety of the patient, the hormonal approach to treatment also requires current appraisal, so that if this proves illusory, opportunity for other forms of treatment in the individual case will not be sacrificed.

Of equal importance with peptic ulcer, and it may not be amiss to say perhaps in the same category, are the inflammatory and ulcerative diseases of the small and large intestines, especially the so-called regional enteritis and nonspecific ulcerative colitis. When attention to the inflammatory and stenosing disease of the small intestine was first called by Burrill Crohn about fifteen years ago, it was thought that this was a specific disease of the terminal ileum. In fact, the name given it was terminal ileitis. Surgical and gastroenterologic observations since that time have shown that this disease process may involve not only the terminal ileum, but any part of the small intestine, either in one part or in patches, with skip areas, and, furthermore, that it may also affect the cecum and ascending colon. In fact, not a few gastroenterologists have expressed the opinion that it may well be essentially the same disease as nonspecific ulcerative colitis. Both diseases share with peptic ulcer the characteristic of tendency to recurrence.

The problem of when surgical treatment should replace medical treatment in these two diseases can be answered only by cooperative observations of both surgeon and gastroenterologist. The possibilities of improvement with continued medical treatment, together with the desire to avoid loss of small intestine or colon and the disadvantages of ileostomy, have to be weighed against the possible spread and further involvement of small intestine and, in both diseases, a possible fatal outcome. The interests of each patient require the greatest degree of cooperative thought and action of both gastroenterologist and surgeon.

The diagnosis of gallbladder disease has undergone varying criteria during the last decade—entirely because of correlation of gastroenterologic and surgical experience. With the exception of the rare polyp, cancer of the gallbladder and empyema without stones, cholelithiasis is the one diagnosis which has been proved an indication for operation. The universally accepted and indispensable Graham-Cole test is interpreted as revealing the presence of stones only if it completely fails to visualize the gallbladder in the absence of an acute condition elsewhere in the abdomen and if it actually shows the stones by consistently appearing radiolucent or opaque shadows. Faint filling, delayed emptying and all the other variations of visualization which were at first thought to be significant of organic disease have been demonstrated by the cooperative observations of surgeon and gastroenterologist to be chimeras, due undoubtedly to transient disturbances in function and not requiring surgical treatment.

The diagnosis of cancer of the digestive tract, in spite of concerted effort of surgeon and gastroenterologist, remains unsatisfactory because it is too often too late. Special effort is now being directed toward that most insidious and most frequently seen form, namely, cancer of the stomach. In about 20 per cent of cases of this disease the lesion first appears in the form of an ulcer, and in these 20 per cent, about one tenth of the lesions have the appearance of a benign ulcer when first seen and must be differentiated from the truly benign ulcer which may be healed and remain healed.

It therefore becomes a matter of vital importance to distinguish between the benign and the malignant or potentially malignant ulcer. Complete healing, as demonstrated by complete disappearance of the crater, gastroscopically and radiologically, and a return of unimpaired flexibility of the wall of the stomach, is the decisive point on which the benign character of the lesion may be judged. But, in addition, the correlated surgical and gastroenterologic experience of the past twenty years has demonstrated that that healing must not be disturbed by recurrence, if this benign character is to be trusted.

In other words, recurrent ulcer must be suspected of harboring cell changes which may transform it to a malignant lesion. This fact indicates the absolute necessity for the most careful follow-up of all gastric ulcers and for resection of all which remain incompletely healed or which recur. This is only one instance of cancer of the digestive tract in which the cooperative efforts of gastroenterologist and surgeon may advance early detection.

The subject, correlation of gastroenterology and surgery, could be elaborated far beyond the points discussed in this paper. But perhaps this discussion may suggest the extent of mutual aid and satisfaction which can be derived from reciprocal relations of these two branches of medicine under ideal conditions of trust and understanding. In conclusion and at the risk of being repetitious, I would exhort the gastroenterologist to follow up his patient through the operating room to his immediate and protracted postoperative life and to keep his surgical colleague well informed on his observations, for the well-being of that patient is the objective of their efforts and excellence of end results is the goal of both.

LONGEVITY IN RHEUMATIC FEVER

Based on the Experience of 1,042 Children Observed Over a Period of Thirty Years

MAY G. WILSON, M.D.
and
ROSE LUBSCHEZ, A.M.
New York

The relative importance of rheumatic fever as a cause of death has been stressed in recent years. It has been estimated that for each death of a person under 20 years of age due to the combined causes of pertussis, diphtheria and poliomyelitis there were 50 deaths due to rheumatic disease of the heart.[1] The United States vital statistics reports for 1944 list deaths from rheumatic fever as 0.1 per 100,000 population and the death rate for rheumatic disease of the heart as 20.4 per 100,000 population, in comparison with the crude death rate of 1,040 per 100,000 for all causes. The Metropolitan Life Insurance Company reported deaths in school children due to rheumatic fever, including rheumatic disease of the heart, as 5 to 6 per 100,000 among industrial policy holders.[2] These mortality statistics emphasize the public health aspects of rheumatic fever, but have limited prognostic value.

Of greater concern to the physician is the determination of longevity in rheumatic fever, i.e., the prospects for an affected child to survive childhood and puberty and to reach adulthood. We have attempted to answer these questions from a consideration of the mortality experience in a group of 1,042 children who have been under our medical supervision during the years 1916-1947. The maximum period of observation was therefore about thirty years for those who came under observation in 1916, and the period of observation was progressively shorter for those whose first observation occurred in later years. Obviously, this time is insufficient for observing the complete life span in every patient, but it is of sufficient length to provide information as to the relative chances of surviving during the first four decades of life.

The conventional method for estimating the chance for survival in specific population groups is by the construction of a life table. The average mortality rates within a stated period following onset are determined (i.e., the ratio of deaths to person years of life experience). From the mortality rates, the risk of death during the specified interval may be determined, and from this figure the chance of survival from the beginning to the end of the interval may be obtained. This method, therefore, permits data as to the chances of survival from onset to any stated period to be accumulated. If these data can be obtained for the entire life span, the average life expectancy, i.e., the average number of years after onset, may be computed. Since our group was under observation for a maximum of thirty years, only a partial life table may be derived, and only the chance of survival to the maximum age in the life table may be ascertained.

The usefulness of the life table technic has been demonstrated by life insurance companies and public health services. Recently, its applicability to prognosis following operative procedures was demonstrated.[3] The methods for constructing abridged life tables have been simplified and are readily applicable to studies of chronic disease. In our studies the abridged life table technic described by Reed and Merrell has been used.[4]

For this study, the records of 1,042 rheumatic patients were reviewed. Eleven per cent of these patients were lost from observation at various points in the follow-up period, but 89 per cent were observed until death or the end of the study (July 1, 1947).

DESCRIPTION OF THE DATA

Before considering the mortality experience of these patients, it is necessary to describe the character of the sample.

Coming under observation from 1916 to 1922 were children referred from the Cornell Clinic. From 1922 to 1932, patients entered the Cardiac Clinic by referral from schools and the New York Nursery and Childs Hospital Children's Clinic and hospital wards. After 1932, rheumatic patients were referred to the Cardiac Clinic from the New York Hospital Children's Clinic and wards. In addition, rheumatic siblings of patients already attending the Cardiac Clinic were brought under observation. Rheumatic patients in whom the onset was presumably after puberty are not included in this series.

All of these patients were under close medical supervision during the entire period of observation, which included adolescence and adult life for those who reached it. About two thirds of the children were from families of the social and economic level usually encountered in a clinic in the city of New York. The remainder were from families of a somewhat higher economic level. The economic level has been higher for the majority of adolescent and adult patients during the past fifteen years.

The diagnostic criteria used in the study conformed to the "Requirements of Cardiac Clinics" of the New York Heart Association. A more detailed description of the medical follow-up of this group has been published.[5]

The age at last observation or at death and the sex distribution of the 1,042 patients is presented in table 1. It will be noted that 257 (25 per cent) were 1 to 15 years of age and that 785 (75 per cent) had reached the ages of 16 to 42 years.

The number of deaths by causes and age groups in which they occurred are summarized in table 2. Within the period of observation, 226 patients died. So far, two thirds of the deaths have occurred in the 1 to 15 year age group. Of the 226 deaths, 75.7 per cent were ascribed to rheumatic disease of the heart and 10.2 per cent to subacute bacterial endocarditis. The incidence of subacute bacterial endocarditis in the entire group of patients was 2.2 per cent. In 37 per

[5] Wilson, M. G.: Rheumatic Fever, New York, The Commonwealth Fund, 1940.

cent of the deaths, verification of the cause of death was obtained by postmortem examination. In most instances, death was due to active rheumatic carditis.

The mean age at onset of rheumatic fever was 6.5 years. The average length of observation in this study was 14.8 years. In the various analyses which were made, no significant sex difference was observed.

The incidence of the various rheumatic manifestations experienced during the course of the disease is presented in table 3. In 7 per cent of the group of 1,042 patients, active carditis occurred as the only manifestation during the observed course, 25 per cent experienced one or more attacks of chorea, 58 per cent had polyarthritis with or without chorea and in 10 per cent there were recurrent attacks of joint pains. In 45 per cent, active carditis occurred in association with other manifestations. A comparison of the various manifestations which characterized the course of the disease by age at last observation reveals that the incidence of active carditis in children who survive puberty is significantly lower in each age group. This is consistent with the natural history of the disease, since death during this period is due to active carditis. Two thirds of the deaths in our series occurred before puberty.

Table 1.—*Distribution of Patients by Sex and Age at Last Observation*

Age (Yr.)	Sex		Patients	
	Female	Male	Number	Percentage
1-15	130	127	257	25
16-19	103	88	191	18
20-29	224	199	423	41
30-42	112	59	171	16
Total 1-42	569	473	1,042	

Cardiac involvement was demonstrable in all of the patients, although active carditis was subclinical in about one half. The cardiac diagnosis for each age group at last observation or death is summarized in table 4. It will be noted that there were multiple valvular lesions in less than half (41 per cent) of the patients between the ages of 20 and 29 and in more than two thirds (71 per cent) of the patients between the ages of 30 and 42. There was moderate or decided cardiac enlargement in about one half of the patients in both of these age groups. It must be emphasized that in about one third of the patients the auscultatory signs of valvular lesions regressed during the period of observation. Auricular fibrillation occurred in 38 patients (4 per cent). Less than half of the patients with auricular fibrillation have survived. In 4 living patients, auricular fibrillation has been present for an average of fifteen years.

Of particular importance is the observation that about 90 per cent of the patients from 20 to 42 years of age were able to carry on their normal activity without circulatory symptoms. One hundred and sixty-seven men served in the armed forces, and 162 women experienced a total of 288 pregnancies.[6] From these figures it is apparent that the morbidity due to rheumatic disease of the heart is low after puberty. This is consistent with a previous observation that the average annual rate of recurrence after puberty is also low (3.7 per cent).[7]

LONGEVITY IN RELATION TO DURATION OF DISEASE

To determine longevity in rheumatic fever, mortality rates were calculated for 1,042 patients representing 15,336.75 person years of life experience. From these rates the probability of survival could be ascertained in relation to the years since onset of the disease and the age of the patient (fig. 1).

In table 5 the mortality rates for the 1,042 patients are presented for specific intervals in the years following the onset of the disease (columns 7 and 8). It is apparent that the highest mortality occurs within the first year after onset. The death rates for one to thirty years after onset are remarkably constant.

Computation of the risk of death during any specified time interval reveals that there are 4 chances in 100 of death occurring within one year after onset of the disease (column 9). The risk of death from the first to the fifth year after onset is 5 chances in 100 and increases to 8 chances in 100 during the fifth to the tenth year after onset. In comparing these risks it must be recognized that the probability of death during an interval is dependent on the length of that interval. Therefore, the chance of death in the first year after onset is about three times as great as in most of the subsequent single years.

There is a slight but significant increase in the risk of death from the fifth to the tenth year after onset in comparison with the previous period. Analysis of this experience by age reveals that in a large proportion of the cases, this is the age of puberty (table 7). It is apparent that the age factor is more important than the time after onset. After the period five to ten years after onset, the rates are remarkably constant. Accumulation of the figures for the risks of death, to give the survival rate from onset to any specified number of subsequent years (table 5, column 10), it may be observed that the fifteen year survival rate is 80 per cent, the twenty year survival rate is 75 per cent and the thirty year survival rate is 66 per cent.

It is interesting to note that the median duration of life (the number of years which half of the children would survive) is evidently considerably greater than thirty years. If the constancy of the rates after puberty should persist for three additional five year periods after thirty years, the median would be about forty-five years after onset. This extrapolation beyond the computed figures appears to be a reasonable assumption.

Table 2.—*Death by Age and Cause*

Age, Yr.	Number of Patients	Total Deaths	Number of Deaths						
			Cardiac Causes		Noncardiac Causes				
			Rheumatic Heart Disease	Bacterial Endocarditis	Tuberculosis	Infectious Diseases	Neoplasm	Accident	Undetermined
1-15	257	138	116	9	2	7	1	3	..
16-19	191	41	29	5	1	1	1	3	1
20-29	423	37	19	8	2	2	..	5	1
30-42	171	10	7	1	..	..	..	2	..
1-42	1,042	226	171	23	5	10	2	13	2

From these observations, it is apparent that there is a decided difference between our figures and those given by Cohn and Lingg.[8] In their study the mean duration of life from onset to death was about thirteen years.

---

[6] Wilson, M. G.; Payson, J. W., and Lubschez, R.: The Experience of Rheumatic Patients in the Armed Forces, Am. J. Pub. Health, to be published.

[7] Wilson, M. G., and Lubschez, R.: Recurrence Rates in Rheumatic Fever, J A. M. A. **126**: 477-480 (Oct. 21) 1944.

[8] Cohn, A. E., and Lingg, C.: The Natural History of Rheumatic Cardiac Disease, J. A. M. A. **121**: 1-8 (Jan. 2) 1943.

They based their figures on an analysis of deaths alone, ignoring the experience of the survivors. This procedure always results in an underestimation of life expectancy. The extent of the underestimation varies inversely with the length of follow-up. This is the severest type of sampling bias, since it is only the persons who die earliest, i.e., the poorest risks, who are used to determine the prognosis figures.

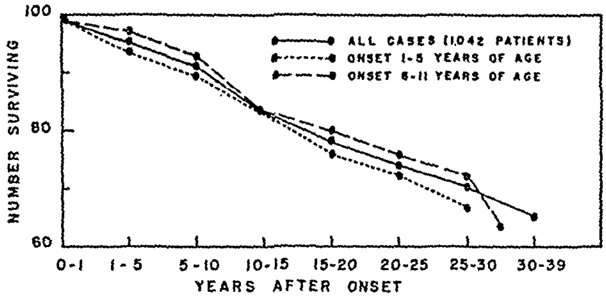

Fig. 1.—Longevity in relation to duration of disease.

It seemed pertinent to determine whether the age at onset is related to the prognosis. Tables were constructed for children with onset from 1 to 5 years and 6 to 11 years of age. Comparison of the mortality rates in the two groups (table 6, columns 7 and 8) revealed that there were no unusual differences according to early or later onset of the disease, demonstrating that the age at onset is not an influential factor.

The over-all comparability of the rates is indicated by the similarity of the survivorship values (table 6, column 10). However, certain differences are noteworthy. There is a higher first year mortality for children who are 1 to 5 years of age at onset, in comparison with those whose onset occurred between the ages of 6 and 11 years. The increased risk of death during the sixth to the tenth year after onset persists to the fifteenth year for those with onset between 1 and 5 years of age and appears earlier after onset among those with onset between 6 and 11 years of age. This again indicates the increased risk at puberty.

LONGEVITY IN RELATION TO AGE

Since it is important to estimate the prognosis of the disease in terms of the age of the patient, age-specific mortality rates were computed for the entire sample (fig. 2). In table 7 (column 9) it may be noted that a mortality rate twice as high as the over-all mortality rate was obtained for children between the ages of 1 and 4 years (33.2 per thousand). A slightly increased rate of 18.2 per thousand was observed for children between the ages of 10 and 14 years, in comparison with the over-all death rate of 14.7 per thousand.

Figures for the risk of death during a specified age interval were computed from these rates and revealed (table 7, column 11) that the probability of death during the period from 1 to 4 years is 11 chances in 100. For children reaching age 5, 7 out of 100 die before reaching age 10. In the group from age 10 to 15, 9 out of 100 who reached age 10 will die, and, in the age group 15 to 20 years, 7 out of 100 die. Of 100 children who reach age 20, 5 die before 25 years, and the risks are the same in the period from 25 to 30 years.

An accumulated survivorship curve may be derived from these risks. Its interpretation is not as clearcut as the survivorship values calculated on the basis of years since onset, which have been considered previously. In the present table, children are entered at various ages, depending on the age at which onset occurred. In spite of this heterogeneity of material, the survivorship values give a prognosis for children whose onset of rheumatic fever occurred subsequent to age 1. Seventy-five per cent of the children survive from age 1 to age 15 and 55 per cent from age 1 to age 40. Of those who survive to the age of 15, 72 per cent survive to age 40.

It seems important to determine whether our sample was representative of the general population in New York in other respects than rheumatic disease of the heart.

The mortality rates from all causes in New York for the years 1919 to 1920 (table 7, column 13),[9] the median year of the sample, were applied to the person years of our sample to obtain the expected number of deaths in our sample (table 7, column 14). It was observed that about twice as many deaths were expected as the total number of deaths from noncardiac causes observed in our sample. Thus, either the sample was not representative of the general population or the careful medical supervision given these patients may have been an influential factor in reducing the number of deaths due to noncardiac causes.

In the past few decades there has been a notable improvement in the general care of children. The mortality rates for children born between 1900 to 1919 and 1920 to 1939 were compared to determine whether there was any significant difference which might be attributed to the improved care of children in recent years.

In table 8 the age specific mortality rates for children born before and after 1919 (columns 9 and 10) are tabulated. Except for three specific age groups, i.e., 1 to 4, 10 to 14 and 15 to 19, there was no significant trend in the mortality rates for the periods before and after 1919. The difference in the age group 1 to 4 years (i.e., 16.3 before and 37.5 after 1919) is associated with such small numbers that it cannot be interpreted. One more death would have equalized the rates. For children born before 1919, the death rates at ages 10 to 14 and 15 to 19 were 26.4 and 22.2 per thousand, respectively, in contrast with 11.9 and 8.2 per thousand for children born after 1919.

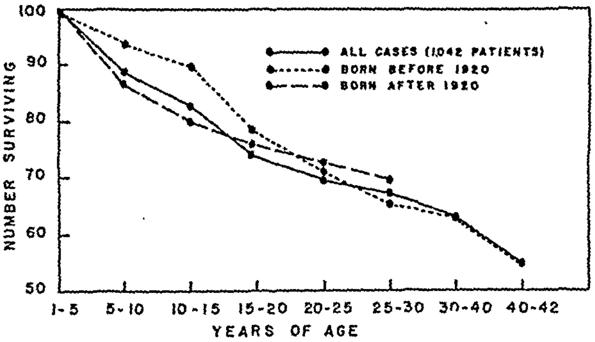

Fig. 2.—Longevity in relation to age.

The differences in the age group 10 to 19 years may in part be attributed to the sources from which the two samples were drawn over the thirty year period of observation.

From 1916 to 1921, only ambulatory children entered from the clinic. Between 1923 and 1930, younger children entered the study from the hospital wards. From 1932 to 1947, sick chil-

---

[9] Summary of Vital Statistics, 1898-1946, Department of Health (New York City), Bureau of Records and Statistics, Statistical Division, 1947.

dren of all ages were referred to the clinic from the hospital wards. Since the ward referrals represent the more severely affected group in our sample and ward referrals did not begin until after 1922, this is reflected in the higher mortality rates in the 10 to 19 age group born before 1920.

Since the differences in the mortality rates for patients born before and after 1920 may be accounted for by differences in the sample, there is no evidence that improved care and nutrition during the past twenty years affected the mortality rate in rheumatic fever.

COMMENT

These observations have the advantage that the medical supervision has been uniform and the patients have been under close observation throughout the entire course of the study.

The sample may be considered representative for rheumatic children living in New York who attend clinics or are admitted to hospitals. The clinical course of the disease experienced by these patients comprised all patterns of rheumatic fever having its onset in childhood.

Interpretation of the mortality rates in rheumatic fever must take into account possible selective factors. Obviously, the mortality rates would be higher if all the patients were drawn from the hospital wards than if selection were limited to clinic attendance. Selective factors may have contributed to the higher death rates in the 1 to 4 year age period in this study because the majority of the children were admitted to the hospital and succumbed to their first severe attack of active carditis. Affected children of this same age group suffering minor manifestations of the disease are small in number and usually are not recognized until a major recurrent attack of rheumatic fever brings them to a clinic for examination.

It must also be borne in mind that analysis of data obtained from a children's clinic cannot be compared with studies derived solely from adult cardiac clinics. In the latter, only historical information is available for the childhood course of the disease. Furthermore, children who did not survive puberty are not represented. There are also likely to be excluded adult survivors who do not attend a clinic because they are not troubled by recurrent attacks of rheumatic fever or circulatory symptoms. This is particularly important, since it has been shown that the morbidity for the 20 to 30 year age period is low.

This study is limited to a consideration of the longevity of affected children for the first four decades of life. The exclusion of patients presumably with onset after puberty is not pertinent.

The complete life expectancy in rheumatic fever has never been presented. To give a complete estimate of the average future lifetime of rheumatic patients, it would be necessary to follow all of a group to death or to use data representative of all ages.

It is possible, however, to determine survival after onset up to the most advanced age observed. In doing this, it is essential to take into account every person who enters the study for as long a time as he is present. The present study is the first analysis of survivorship in rheumatic fever which takes these factors into account.

It must be borne in mind that during childhood death is due to active carditis. The severity of any one attack and the number of recurrent attacks with resultant cardiac damage influence the ultimate prognosis in each patient.

The low mortality and morbidity rates after puberty among the survivors should be emphasized. Although there was demonstrable cardiac involvement in all of the patients, 90 per cent were able to carry out their normal activity at last observation.

It is of interest that the improvement in general care and nutrition in the past few decades did not appear to be reflected in decreased mortality rates for the children born after 1920.

SUMMARY

The records of 1,042 children who were under observation over a thirty year period of observation, from 1916 to 1947, are reviewed. Eighty-nine per cent of the patients were seen at death or at the end of the study.

The mean age at onset was 6.5 years. The average length of observation was fourteen and eight-tenths years.

At last observation, 25 per cent (257) were between the ages of 1 and 15 years and 75 per cent (785) were from 16 to 42 years of age.

Among 226 deaths, 75.7 per cent were due to rheumatic disease of the heart and 10.2 per cent to subacute bacterial endocarditis. The incidence of subacute bacterial endocarditis in this series of 1,042 patients was 2.2 per cent.

The clinical course of the disease was characterized by active carditis alone in 7 per cent. In 25 per cent there were one or more attacks of chorea; in 58 per cent polyarthritis occurred with or without chorea, and 10 per cent had joint pains. Active carditis was clinically recognizable in only 45 per cent of these patients.

Cardiac involvement was demonstrable in every patient at last observation. Multiple valvular lesions and moderate or decided enlargement of the heart was observed in about one half of the patients. Auricular fibrillation occurred in 4 per cent of the patients.

There was regression of auscultatory signs of valvular lesions in one third of the group.

Ninety per cent of the patients who were 21 to 42 years of age at last observation were able to carry on their normal activity without circulatory symptoms. One hundred and sixty-seven men served in the armed forces, and 162 women experienced a total of 288 pregnancies.

The mortality experience among 1,042 rheumatic patients representing 15,336.75 person years of life experience is presented.

Analysis revealed no significant sex difference in the age-specific mortality rates.

The mortality rates indicate that there is an increased risk at puberty irrespective of age at onset of the disease. The highest mortality rate occurred within one year of onset.

The over-all death rate was 14.7 per thousand per year.

The highest death rates occurred between the ages of 1 and 4 years (33.2 per thousand) and 10 to 14 years (16.3 per thousand).

A comparison of age-specific mortality rates for children born before and after 1919 showed no difference attributable to improvement in general care and nutrition during the past twenty years.

The longevity in rheumatic fever for the first four decades of life is presented.

An affected child has 4 chances out of 5 to survive fifteen years after the onset of the disease, 3 chances out of 4 to survive twenty years after onset and 2 chances out of 3 to survive thirty years after onset.

The median duration of life for rheumatic children is greater than thirty years after onset.

An affected child has 4 out of 5 chances to survive childhood (to the age of 10 years), 3 chances out of 4 to survive puberty and 19 chances out of 20 to survive early adult life.

The over-all chance to survive to the age of 40 years is 1 out of 2.

525 East Sixty-Eighth Street.

APICAL PULMONARY CARCINOMA AND TUBERCULOSIS

The Value of Sputum Cell Study in the Differential Diagnosis

MARTIN BERGMANN, M.D.
BURTON A. SHATZ, M.D.
and
I. JEROME FLANCE, M.D.
St. Louis

The differentiation of apical pulmonary tuberculosis from apical pulmonary carcinoma on clinical and radiologic grounds is often difficult. Since as high as 52 per cent of all carcinomas of the lung occur in the upper lobes,[1] this differentiation is a perplexing and not infrequently occurring problem. The location of these lesions frequently prevents the bronchoscopist from obtaining a biopsy specimen or even visualizing the pathologic process.[2] Since tuberculosis is usually treated medically, whereas carcinoma demands early radical surgical treatment, an accurate diagnosis is of extreme importance. In 1943 a series of 164 cases of carcinoma of the lung reported by Overholt [3] revealed that 63 per cent were misdiagnosed by the first physician consulted. In this group of pulmonary carcinomas, tuberculosis was the incorrect diagnosis in 38 per cent. In a report of the mistaken diagnosis of tuberculosis as encountered in a sanatorium by Kaplan and Levin,[4] carcinoma of the lung accounted for 18 per cent of the misinterpreted pulmonary lesions. These figures indicate the frequency with which this problem arises. Therefore, any additional procedure which helps to reduce the incidence of this not uncommon diagnostic error would be of the utmost value.

Exploratory thoracotomy, a rather drastic procedure for obtaining a biopsy specimen, needle aspiration, with its dangers and inadequacies,[5] and bronchoscopy, with its difficulty in visualizing the upper lobes, have heretofore been the only methods of procuring tissue for diagnostic study. The work of Dudgeon and Wrigley [6] and others [7] has established the examination of sputum for tumor cells as a procedure which will yield a positive diagnosis in from 60 to 88 per cent of carcinomas of the lung. However, the place of this diagnostic aid in the specific problem of the differentiation of apical tuberculosis from apical cancer has not been duly emphasized.

In the past several months we have examined the sputum of 158 patients, employing the technic described by Wandall.[7c] Three cases in this series were of special interest in that a diagnosis of carcinoma was made by sputum examination, at a time when the clinical diagnosis was tuberculosis or wavered between tuberculosis and carcinoma.

REPORT OF CASES

CASE 1.—A 60 year old white salesman had been under a physician's observation since the death of his two sisters from tuberculosis four years previous to his admission to the hospital. During this time he had had a chronic cough, productive of small amounts of grayish white sputum. From a roentgenogram of the chest taken one year prior to admission, diagnosis of an active tuberculous process was made. However, the patient continued to feel well until three months before admission, when increasing exertional dyspnea, increased cough and weakness developed. He lost 6 pounds (3 Kg.) during this period. He was finally admitted to the hospital after an episode of severe pain in the right side of the chest.

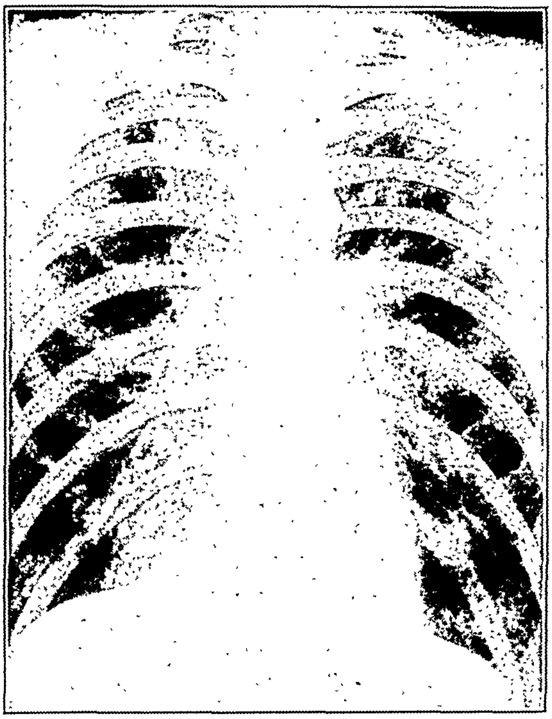

Fig. 1 (case 1).—Roentgenogram of the chest one year before diagnosis of carcinoma was made, showing infiltrate in the upper lobe of the right lung with suggestion of cavitation.

Aided by the David May-Florence G. May Fund.

R.: Bronchogenic Carcinoma: Diagnosis by Microscopic Examination of Sputum and Bronchial Secretions; Preliminary Report, Proc. Staff Meet., Mayo Clin. **22**:369-381 (Sept. 3) 1947.

Physical Examination.—The patient's temperature was 98.6 F. and pulse rate 90; respirations were 20. He was undernourished. The noteworthy observations were limited to the chest. Expansion was the same on both sides. Over the upper lobe of the right lung, anteriorly, tactile fremitus was slightly impaired, percussion note was dull, breath sounds were diminished and occasional expiratory moist rales were heard.

Laboratory Observations.—The red blood cell count was 5,400,000, hemoglobin 104 per cent, and white blood cell count 15,400, with a slight shift to the left in the differential count. Results of sputum examinations for acid-fast bacilli were negative. The remainder of the laboratory observations were within normal limits.

A review of the roentgenograms obtained from the patient's physician (taken three years before admission) revealed the presence of increased peribronchial markings, extending from the hilus to both apexes. One year before admission a 3 by 2 cm. subapical infiltrate was seen in the upper lobe of the right lung. This contained a small area of rarefaction, suggesting early cavitation (fig. 1). A roentgenogram of the chest taken on admission showed a decided increase in size of the area of infiltration. A bronchoscopic examination was made the day following admission, and no endobronchial lesion could be detected. However, some sputum was aspirated from the right main bronchus. Examination of these secretions showed the presence of one clump of 5 large atypical epithelial cells. Their nuclei were relatively large and hyperchromatic and contained prominent deeply stained nucleoli. The diagnosis was neoplastic cells in the sputum (fig. 2).

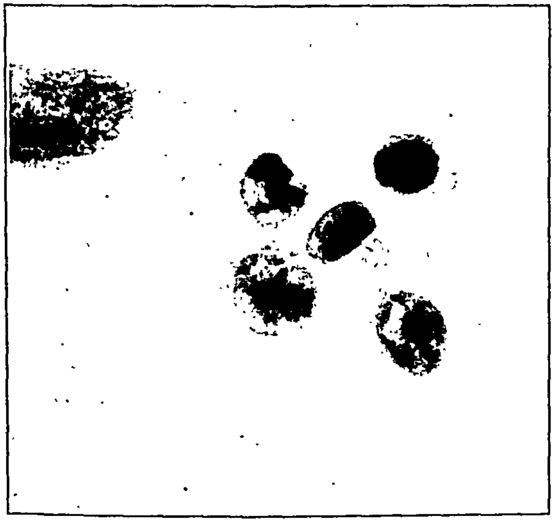

Fig. 2 (case 1).—Five large cancer cells with large nuclei and nucleoli in the sputum (hematoxylin and eosin stain, × 1,320).

A right pneumonectomy was attempted. The lung was observed to be adherent to the anterior thoracic wall, and there was mediastinal infiltration. A small piece of pleural adhesion was obtained for biopsy. Severe hemorrhage was encountered in attempted separation of the lung from the thoracic wall. Despite all the usual measures, including massive transfusion, the patient went into shock and died. At autopsy an orange-sized tumor was seen in the upper lobe of the right lung. Microscopic examination of the specimen obtained at operation showed fibrous tissue invaded by small cords of anaplastic hyperchromatic epithelial cells. The diagnosis was bronchogenic carcinoma, undifferentiated.

Case 2.—A 57 year old white male coffee packer entered the hospital complaining of cough, weakness and weight loss of 27 pounds (12 Kg.) during the previous year. During this period he had had frequent colds, chills, fever and night sweats. Two months before admission his cough became productive of blood-streaked sputum, and one week prior to admission he had had a frank hemoptysis of "2 cups" of blood. His brother, with whom he lived, died of pulmonary tuberculosis; his mother died of "pneumonia."

Physical Examination.—The blood pressure was 155 systolic and 90 diastolic, temperature 100.8 F. and pulse rate 68; respirations were 24. The patient was a well developed poorly nourished white man of 57, who appeared chronically ill. Noteworthy observations were confined to the chest and extremities. Over the upper half of the right side of the chest, anteriorly and posteriorly, there were increased tactile and vocal fremitus, dulness to percussion, decreased breath sounds and whispered pectoriloquy. The extremities showed moderate clubbing of fingers and toes.

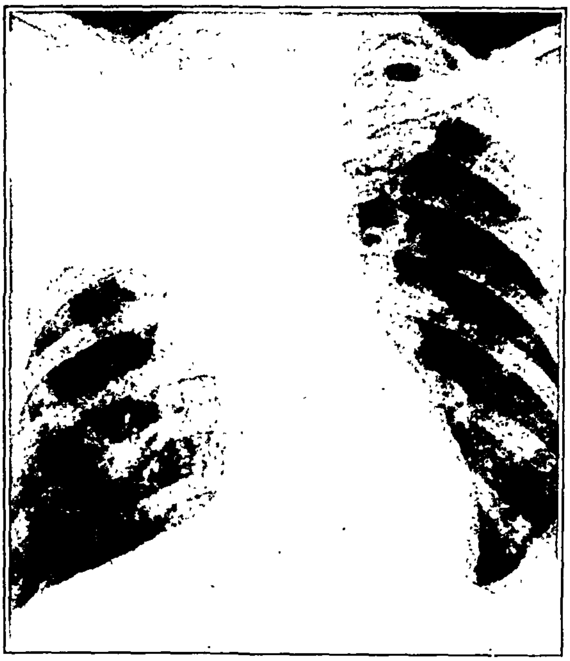

Fig. 3 (case 2).—Roentgenogram of the chest, showing upper lobe consolidation in the right lung. This was thought to be tuberculous pneumonia.

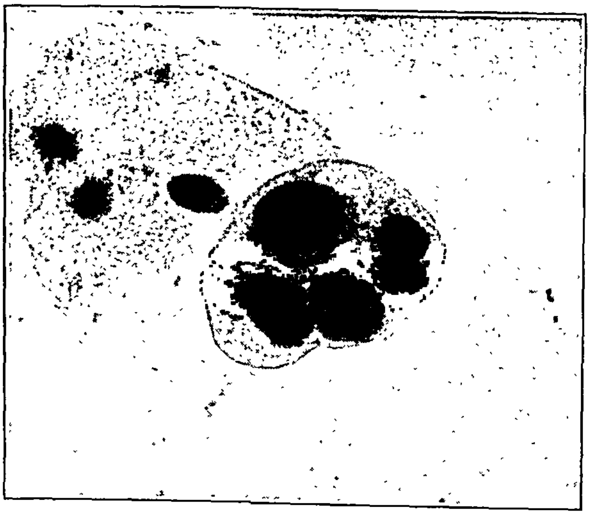

Fig. 4 (case 2).—Clump of hyperchromatic malignant cells in the sputum. Large nuclei and one large nucleolus are visible (hematoxylin and eosin stain, × 1,320).

Laboratory Observations.—The white blood cell count was 15,900, without appreciable shift in the differential count. The Kahn and Wassermann reactions were positive. Three sputum examinations failed to reveal acid-fast bacilli. Roentgenograms of the chest, taken on admission, showed a consolidation of the upper lobe of the right lung. This opacity was not homogeneous and contained small round shadows of decreased density. The trachea was slightly deviated to the right. These observations were thought to be consistent with consolidation in the upper lobe of the right lung, probably tuberculous in origin (fig. 3). Sputum examination revealed the presence of clumps of large epithelial cells of varying size. The nuclei were hyperchromatic and varied in size and shape. One or more deeply staining nucleoli were present in each nucleus. The diagnosis was neoplastic cells in the sputum (fig. 4).

Subsequently three bronchoscopies were done. Irregular thickening of the right mainstem bronchus up to and including the carina was seen. Three specimens obtained for biopsy failed to reveal cancer. The patient was considered inoperable, despite the negative results of biopsies, because of the bronchoscopically observed carinal involvement. He was given palliative roentgen therapy, but died three months after the diagnosis was made. At autopsy the upper lobe of the right lung was almost completely replaced by a firm grayish white tumor mass. A tumor thrombus occupied the pulmonary vein and extended into the left atrium. Metastases were seen in the right hilar lymph nodes, the right adrenal gland and the right kidney. Microscopically the tumor was composed of anaplastic spindle-shaped epithelial cells with prominent nucleoli. There was extensive fibrosis and necrosis, probably the result of the roentgen radiation. The diagnosis was bronchogenic carcinoma, squamous cell type.

Case 3.—A 49 year old white salesman complained of a chronic productive cough for the ten years prior to admission. He brought up about half a cup of mucoid sputum, but had no hemoptysis, night sweats, fever, chills or weight loss. Five days before admission he coughed up a small blood clot, and thereafter on one or two occasions the sputum was slightly blood streaked. There had been no hemoptysis since. Also for the past three to four months he had noted increasing clubbing of his fingers. From a roentgenogram of the chest, taken by his physician, the diagnosis was pulmonary tuberculosis.

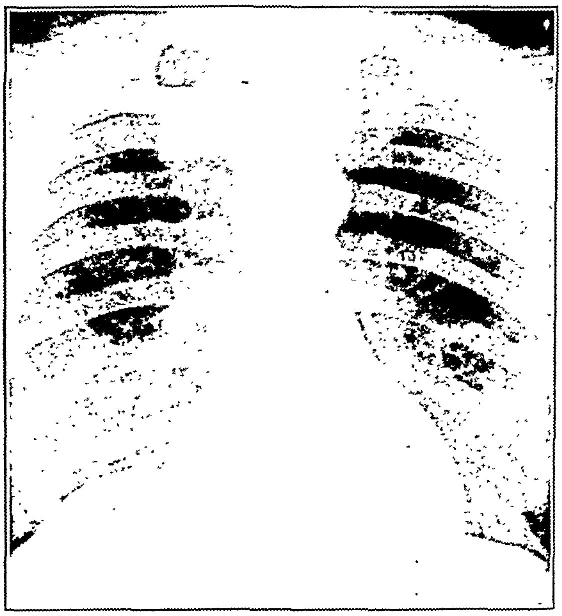

Fig. 5 (case 3).—Roentgenogram of the chest, showing infiltrate of the upper lobe in the right lung. The diagnosis was subapical tuberculosis.

On admission physical examination showed a blood pressure of 130 systolic and 80 diastolic, temperature 99 F., pulse rate 76 and respirations 20. The patient was well developed and well nourished and appeared to be in good health. The chest was normal to percussion and auscultation The extremities showed decided clubbing of the fingers and toes. The results of the remainder of the physical examination and the laboratory observations were not remarkable. A roentgenogram of the chest showed an area of increased density in the upper medial portion of the right lung, measuring about 6 by 5 cm. This density was continuous with the upper aspect of the right hilar shadow. The chest was otherwise entirely normal (fig. 5). The sputum was examined on the day following admission. It contained numerous clumps of large epithelial cells, which varied significantly in size. The nuclei were large and hyperchromatic, and some of the cells were multinucleated. In almost all of the nuclei one or more large deeply staining prominent nucleoli were present. The diagnosis was neoplastic cells in the sputum (fig. 6). Bronchoscopic examination was entirely without significant observations.

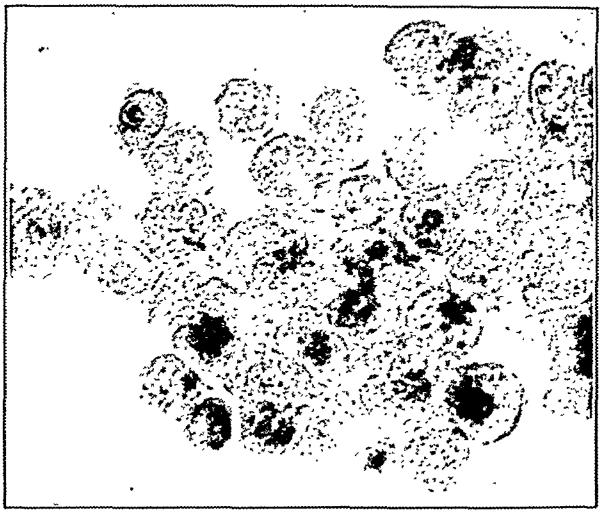

Fig. 6 (case 3).—Portion of a large clump of tumor cells in the sputum. The cells vary in size, and the nuclei and nucleoli are large (hematoxylin and eosin stain, × 1,320).

A right pneumonectomy was done by Dr. Mudd. Gross examination of the lung revealed a tumor arising from a secondary division of the upper lobe bronchus in the right lung, about 4 cm. from the main bronchial orifice. Microscopic examination of the tumor showed cords of anaplastic epithelial cells, which varied decidedly in size and shape. The cells had large vesicular nuclei and prominent nucleoli. The lymph nodes showed no evidence of metastases. The diagnosis was bronchogenic carcinoma, undifferentiated.

COMMENT

The cases presented exemplify the problem in the differential diagnosis of apical pulmonary disease and the aid that may be derived from the examination of sputum for tumor cells. Since tubercle bacilli are frequently not seen in early pulmonary tuberculosis, this diagnosis is often made on the basis of clinical and radiologic observations, without a serious attempt to exclude carcinoma. Furthermore, even when tubercle bacilli are identified in the sputum, the occasional coexistence of active tuberculosis and carcinoma must be borne in mind. Although this association had been uncommon, it may be encountered with greater frequency in the future as the life expectancy of tuberculous patients increases. Apical carcinoma must also be considered in a known arrested case of tuberculosis, when a change in the pulmonary lesion is demonstrated by roentgen examination. This is especially true in the older age groups.

Until recently the clinician has depended primarily on bronchoscopic biopsy for the diagnosis of pulmonary disease when the roentgenologic observations were inconclusive. However, bronchoscopic examination has several inherent shortcomings. The percentage of positive results of biopsies which can be obtained through the bronchoscope in proved cases of pulmonary carcinoma, irrespective of location, is only 42 to 62 per cent.[8] The percentage of failures is especially high when the lesions are situated in the upper lobes, for, unless the tumor is within a very short distance of the upper lobe bronchial orifices, it is beyond the reach of the endoscopist. While needle aspiration biopsy of the lung is a valuable procedure, we feel that it is too uncertain a method for use in the differential diagnosis of apical pulmonary lesions. The danger of entering a possible tuberculous lung or producing needle tract tumor transplants, not to mention its other complications, renders it unsuitable for this type of case. Exploratory thoracotomy should be employed only when all other means of diagnosis have been exhausted.

The outlook for patients with pulmonary carcinoma continues to be rather poor [9] and can be improved only by an accurate diagnosis early in the course of the disease, when resection is still possible. The examination of sputum for tumor cells offers a means of quickly establishing a histologic diagnosis. In our experience the incidence of tumor cells in the sputum has been highest in lesions of the upper lobes of the lungs, probably because of the better drainage of bronchial secretions from the upper lobes into the main bronchi, where they are readily expectorated. Thus, in the very cases in which bronchoscopy is oftenest of no help the sputum examination is most likely to give positive results. In the older age groups especially, sputum examination for neoplastic cells should be employed almost as routinely as the examination for tubercle bacilli in the diagnosis of apical pulmonary lesions.

SUMMARY AND CONCLUSIONS

Three cases are presented in which the observation of tumor cells in the sputum established a diagnosis of carcinoma of the lung when, clinically, tuberculosis was suspected.

Microscopic examination of the sputum for neoplastic cells is an important aid especially in the diagnosis of apical pulmonary lesions. In patients of the cancer age examination of sputum for the diagnosis of apical lesions should routinely include a search for tumor cells.

Six Years of Profound Changes.—The last six years have seen the initiation of more profound changes in scientific medicine than any period since the discovery of bacteria or the invention of the microscope. This change has been brought about by many factors: the wholesale uprooting incident to the war, the development of antibiotics, the impact of social legislation, but above all the advent of atomic energy. . . . When we think that six years ago the average man had no more concern with ionizing radiation than as a means of checking on an aching tooth or determining the cause of chronic cough, whereas today millions of people live within the shadow of possible war-time exposure to ionizing radiation from the atomic bomb; when we realize that six years ago it would be a skilled chemist who could detect after hours of work a millionth of a gram of phosphorus and now a technician with a Geiger counter can detect a fraction of a millionth of a gram of radioisotopic phosphorus in a few minutes, we can realize how long a road we have come in this short span.—Warren, Shields, M.D., *Bulletin of the Atomic Scientists*, August 1948.

DISEASES OF THE LACRIMAL GLAND AND OCULAR COMPLICATIONS

JOHN A. MacMILLAN, M.D.
Montreal, Canada

For some years I have been interested in the lacrimal apparatus, at first mainly in the drainage of the lacrimal secretion, but more recently the lacrimal gland itself and its functions, together with some of its pathologic states. So much is unknown in this field that I thought I might attempt to gather a few of the known fragments and present them.

The lacrimal gland which secretes most of the tears in the conjunctival sac consists of two lobes; the orbital, the larger, about 20 mm. long, 12 mm. wide and 5 mm. thick, and the palpebral lobe, which is about one-half to one-third the size of the orbital one. It is wedged between the globe and the orbital wall, and the aponeurosis of the levator muscle is responsible for dividing it into the two lobes as the gland encircles its outer edge. This is well to remember when operations are to be performed either on the gland or on the muscle. According to Whitnall,[1] the lacrimal gland is a tubular racemose gland consisting of a mass of lobules, each lobule being made up of a collection of ramifying tubes, and each tube branching further into tubules or acini around a central canal the cells of which lie on a basement membrane. The large secreting type of cell occupies most of the acini and appears in different aspects, according to its secretory activity. The other type of cell is the flat myoepithelial cell, or the basket cell or so-called korbzelle, about which I shall speak later. Although there is a divergence of opinion about the appearance of the secretory cells and their secretory granules, it would seem that the function of the two kinds of cells is agreed on, namely, that the large cells secrete tears and the basket cells, by contracting, expel the secretion into the tubules. The tubules, which at first are intralobular, by joining with others become extralobular or collecting canals. These, by further joining, become the ducts of the gland, which are usually not more than twelve in number. The majority of these ducts come from the inferior lobe. They open into the conjunctival sac, mostly in the upper-outer angle of the fornix above the upper border of the tarsal plate, although one or two extend below the external ligament and open in the lower-outer part of the conjunctival sac. These lower ones are responsible for the occasional cyst found in this region. The ducts of the orbital gland usually traverse the inferior lobe in their course, which is an important anatomic point in the surgical treatment of excessive tearing by removal of the inferior lobe of the gland.

The cells of the acini are of a columnar shape and resemble the serous or albuminous cells of the salivary glands. There are no cells in the lacrimal gland comparable to the mucous cells of the salivary glands. The columnar cells contain fat droplets and large pale secretory granules which change in number, depending on the volume of the cell according to the stage of secretion.[2] Between these cells and the basement membrane, basket cells are to be seen. It is *difficult*, or impossible, to make out the outline of the cell bodies

in ordinary sections; but the nuclei are long and spindle shaped and can be easily seen. The smallest intralobular excreting ducts are lined by a layer of low columnar or cuboidal cells and have a few myoepithelial cells. The large intralobular ducts have two layers of epithelium. Beattie and McDonald[3] found that there were two separate secreting units in the lacrimal gland of cats: the alveoli and the secretory ducts. They expressed the belief that the alveoli were responsible for the secretion of large quantities of watery fluids, while the ducts secrete a fluid which contains a high percentage of solids. There is no evidence, however, that such exists in human beings.

NERVE SUPPLY

The nerve supply of the lacrimal gland is well known in that the fifth, seventh and sympathetic fibers reach the gland, but the manner in which they do this and the role which each plays are still unsettled. The fifth nerve supply is through the lacrimal nerve, the smallest branch of the ophthalmic or first division of the fifth cranial nerve. It enters the orbit through the lateral part of the superior orbital fissure, runs along the upper border of the lateral rectus muscle with the lacrimal artery and enters the gland and gives off twigs to the gland and to the conjunctiva. It receives a twig from the zygomaticotemporal branch of the zygomatic nerves, which is a branch of the maxillary or second division of the fifth cranial nerve. This twig is believed to contain secretomotor fibers from the sphenopalatine ganglion. This is disputed by some, especially Kalt,[4] as the zygomatic nerve leaves the maxillary nerve before the fibers from the sphenopalatine ganglion enter the maxillary nerve. For these fibers to enter the zygomatic nerve they would have to course backward in the maxillary nerve to run forward in the zygomatic nerve. The facial nerve supply is through the greater superficial petrosal nerve which arises from the geniculate ganglion of the facial nerve. Although it is made up chiefly of sensory fibers it probably contains a few parasympathetic fibers which go to the splenopalatine ganglion.[5] It leaves the geniculate ganglion and passes beneath the gasserian ganglion to reach the foramen lacerum, where it joins the deep petrosal nerve from the sympathetic plexus on the internal carotid artery and becomes the vidian nerve which ends in the sphenopalatine ganglion. From here the fibers from the facial proceed as previously described, by way of the zygomatic nerve and others by way of the orbital branches from the sphenopalatine ganglion. These latter are two or three delicate filaments which enter the orbit through the inferior orbital fissure and are distributed to the periostium and orbital muscle. Some fibers are said to convey secretomotor fibers to the lacrimal gland. This is the more direct pathway.

The sympathetic pathway seems to be along two courses: One is by way of the deep petrosal nerve from the internal carotid plexus which joins with the greater superficial petrosal nerve to join the sphenopalatine ganglion, and from there on the course is similar to that of the facial fibers. A second route is by way of plexuses along the internal carotid artery and its branches, that is, following the lacrimal artery to the gland.

If the course of the nerve fibers to the lacrimal gland, as mentioned previously, is not entirely agreed on, the role played by each in activating secretion is even more disputed. The general belief is that the sympathetic is responsible for the ordinary amount of fluid necessary for the physiologic requirements of the eye, that the facial supplies the excessive tearing and that the fifth nerve is an afferent pathway.

Babkin, however, said that all investigators agree that the secretory parasympathetic fibers for the lacrimal gland in human beings are derived from the nucleus salivatorious superior of the seventh nerve in the medulla and pass through the greater superficial petrosal nerve to join one of the trigeminal branches and reach the gland, presumably by way of the zygomatic and lacrimal nerves. It seems that the fifth nerve sends only sensory fibers to the eye and forms the afferent path of the lacrimal reflex. It is doubtful that secretory fibers originate in the nucleus of the fifth nerve.

The role of the sympathetic nerve in lacrimation is especially obscure. It is almost impossible to produce any secretion of tears by sympathetic stimulation. Certainly the sympathetic conveys vasodilator and vasoconstrictor fibers to the lacrimal gland, and it may convey motor fibers for the basket cells of the acini and tubules. This is only a supposition, as no detailed work on the secretory mechanism of the lacrimal gland in human beings has ever been carried out.

CONDITIONS ASSOCIATED WITH DIMINISHED TEAR SECRETION

Keratoconjunctivitis Sicca.—Probably the best known of the conditions associated with diminished tear secretion is keratoconjunctivitis sicca. This disease has been well described by Sjögren[6] in his extensive monogram, and a more recent contribution on the subject was given by Bruce, in 1941.[7] I do not intend to describe the condition in detail, as this is well done in the aforementioned articles, accompanied with an excellent bibliography. The commonest complaints are burning and itching of the eyes, with impaired vision at times. There is usually a dry feeling as well, and photophobia is often present. Usually there is stringy mucus present in the conjunctival sac which is difficult to remove, not unlike that seen at times in spring catarrh. This should lead to a suspicion of the diagnosis of keratoconjunctivitis sicca, and tear measurement should always be carried out. Dryness of the mouth is not always complained of, but on inquiry it is usually admitted. Similarly, swelling of the parotid gland and arthritis are often acknowledged only after inquiry. The flakes of mucoid material adhere to the cornea, and they are moved about only after a good deal of pressure through the lid. These may be mistaken for true filaments, which are usually found on the lower part of the cornea during some stage of the disease. Many of the cases reported have occurred in women about the menopause. I recently saw a patient, aged 37 years, who had had an artificial menopause produced twelve years previously; keratitis sicca developed two years after menopause, with no relief through general and local treatment until occlusion of the canaliculi, as first advised by Beetham,[8] was performed, after which practically all her symptoms disappeared immediately. In a case in which I closed the canaliculi on one side only, the patient insisted on having the other similarly treated as soon as possible. This is done by inserting an electrocoagulation needle into the canaliculus for 3 or 4 mm., and sufficient current is used to destroy the epithelium so as to lead to closure. This method of treatment is so satisfactory that it should be instituted as soon as the diagnosis is made and the symptoms are distressing. Pathologic study of the condition in its early stages, as described by Sjögren,[9] shows that some of the granular tubules are replaced by a granular mass of protoplasm with no cell boundaries and the *nuclei are found in irregular* groups. Later the cells lose their connection with one another and lie like masses of free round cells. This is followed by the migration of round cells, and there is gradual conversion of the whole gland into connective tissue. Giant cells have never been seen. Nothing is mentioned of the condition of Krause's glands. It is presumed that similar changes occur in them.

Neuroparalytic Keratitis.—Perhaps the second most common condition associated with diminished tear secretion is neuroparalytic keratitis, or, as Rowbotham [10] called it, "paralytic interstitial keratitis." This at times follows operation or alcohol injection for the relief of fifth nerve neuralgia. It has never been reported in cases where the sensation of the cornea is preserved; that is, unless the ophthalmic division of the fifth nerve is physiologically severed. I feel that we, as ophthalmologists, should impress this on the neurosurgeons and endeavor to have them spare the ophthalmic division of the fifth nerve, or the fibers leading to it, if at all possible in operations for the relief of trigeminal neuralgia. The incidence of neuroparalytic keratitis, after complete section of the posterior root, or destruction of the ganglion by alcohol, is difficult to determine, as it may occur many years after surgical intervention. Harris [11] expressed the belief that it probably occurred in about 20 per cent of the cases. Others say 10 per cent, but both these figures seem high. Severance of the greater superficial petrosal nerve diminishes tear secretion, and Verhoeff [12] expressed the belief that this is probably responsible for the occurrence of the keratitis; yet I have seen the keratitis appear where the greater superficial petrosal nerve could not have been injured and the seventh nerve was also completely intact. Also, I have not seen a corneal lesion occur in a patient in years of follow-up after all the nerve supply to the lacrimal gland had been severed except some of the sympathetic supply. To relieve the persistence of severe pain due to right-sided fifth nerve neuralgia, Dr. William Cone carried out the following procedures in a case: a partial section of the fifth cranial nerve by the subtemporal approach, resection of the greater superficial petrosal nerve by the same approach, complete section of the fifth nerve through the occipital approach, removal of the superior cervical ganglion and, finally, section of the glossal pharyngeal nerve and the second, third and fourth cervical nerves on the right side. As the stellate ganglion was not removed, sympathetic fibers probably still entered the gland. There was anesthesia of the cornea, but, in spite of all this, tears were still present and the cornea remained normal for nine years, until the patient's death a few months prior to the time of reporting. The patient was addicted to drugs and alcohol, so that adequate protection of his eye could not have been adhered to. In neuroparalytic keratitis, which I believe is due to drying from lack of tear secretion, there is a loss of epithelium, but I have never seen filaments present as one sees in keratitis sicca. The area heals immediately when the lids are sutured together, and it remains so as long as they are left closed. A patient with neuroparalytic keratitis,[13] after the closed lids were separated and the puncta occluded, remained well for twelve years. On account of this satisfactory result, which has held for such a long period, I feel that closure of the canaliculi may have as important a place in this condition as it has in the treatment of keratoconjunctivitis sicca.

Corneal Lesions.—Corneal lesions are reported in the literature following removal of the lacrimal gland, but in most of them there seemed to be other factors in which the accessory glands or their secretory fibers have been involved. I still believe that the lacrimal gland, orbital and palpebral lobes, may be removed with safety when Krause's glands are not affected. I have never seen a case of congenital absence of the lacrimal gland or absence of its secretion, as reported by Duke-Elder.[14]

Protein Content of Lacrimal Secretion.—Charlton [15] stated that the protein content of the lacrimal secretion has considerable practical application in the nourishment of the anterior layers of the cornea, and Gundersen [16] stated that complete peritomy does not cause any visible disturbance in the corneal epithelium, and he stated the belief, in view of this and other experimental evidence and in view of the fact that tears are rich in sugar and nitrogenous substance, that it is probable that the epithelium derives its nourishment chiefly from the lacrimal secretion. I have felt that the healing of corneal lesions in neuroparalytic keratitis by closure of the lids was at least partly due to the better nourishment received by the epithelium from the contact of the palpebral conjunctiva and that the healing was not simply due to protection alone.

Oversecretion of Tears.—Oversecretion of tears is a much commoner complaint. During winters in Montreal, one hears of this complaint daily. It is chiefly limited to the older age groups, and is not due to any fault of the drainage apparatus but to overproduction of tear secretion. I think that probing is bad practice in this type of case. If the tearing is troublesome enough, removal of the inferior lobe of the gland should be performed, and in my experience this gives satisfactory results.

Disease of the Lacrimal Sac.—One cannot consider the problem of excessive tearing without considering disease of the lacrimal sac. Tearing after proper excision of the lacrimal sac is not as common as is believed. Paparcone [17] found only 4 or 5 patients with troublesome epiphora in 302 cases after extirpation of the tear sac. I have often felt that in many cases, after a clean excision of the sac without injury to the canal walls, some tears must escape into the nose. If the epiphora is troublesome, excision of the inferior lobe usually gives satisfactory relief. In elderly persons, and in those distant from expert care, when dacryocystitis is present I feel that excision of the sac, on account of its ease, is the operation of choice, but in younger persons a conservative operation should be carried out. I have never performed a dacryostomy, as advised by Arruga,[18] although I have seen 1 patient for whom the operation was performed with success. Occasionally, in troublesome tearing, when all other means of treatment have failed, excision of the lacrimal gland is advisable. An instance of this is the case of J. S. L., aged 42 years, a clerk, with troublesome tearing of both eyes for years. He gave a history of having had some form of conservative operation performed on his right lacrimal sac with excision of the inferior lobe of the right gland, with no relief. He also had left-sided chronic suppurative dacryocystitis. I removed the left sac, and after this operation there was no epiphora in the left eye. One year later I removed the remains of the right inferior lobe of the lacrimal gland, but tears were still troublesome, and seven months later I removed the right orbital gland, with immediate relief, and recent correspondence reveals that he has remained free from tearing. The right lacrimal sac was not interfered with, as there was no regurgitation of pus and both canaliculi, which had been slit, were tied down in the scar.

Excision of the lacrimal gland is not difficult but does not seem to have met with much favor, possibly on account of the radical procedure reported by Holmes,[19] in which he removed the orbital gland at the time of the excision of the lacrimal sac.

Crocodile Tears Syndrome.—The crocodile tears syndrome is believed to be due to misdirection of fibers in regeneration of the seventh nerve after paralysis. Fibers intended for the parotid gland are diverted to the lacrimal gland, so that during mastication the salivary nucleus is also bombarding the lacrimal gland with the secretomotor stimuli.

Lysozyme.—In 1922, Fleming[20] described its presence in large quantities in the tears. Lysozyme is an enzyme with decided bacteriolytic properties, and, according to Ridley,[21] when it is present in full concentration it is capable of inhibiting the growth of all the common pyogenic cocci which may infect the eye. As lysozyme is impaired in its action by way of the common chemicals used as eye drops, Fleming[22] said that better results might be obtained if less attention were paid to the bactericidal action of chemical antiseptics and more care given to the bacteriostatic action, that is, the inhibition of growth of bacteria. I believe that this is a point which is too often forgotten.

TUMORS OF THE LACRIMAL GLAND

Tumors of the lacrimal gland are relatively rare, but not so uncommon as to be classed as curiosities. Lane[23] collected 229 cases up to 1922, and Ziporkes[24] said that about 275 cases were reported up to 1937. My colleagues and I have had 3 cases of tumor of tl lacrimal gland[25] at the Royal Victoria Hospital, Mo treal, the report of which follows.

CASE 1.—Mrs. E. M., aged 64 years, had experienced pa in the left eyeball, on and off, for thirty years following blow. The first sign of proptosis was in August 1930. Fo months later there was a mass in the upper-outer angle the orbit, which was removed. One year later there was rec rence; partial exenteration of the orbit, with removal of ove lying bone, was done. The patient died from intracran extension eight years after the first operation.

The histologic sections showed a central distinctly malignant area with closely packed cells arranged to form acini and cystic space, giving a cribiform appearance. At the periphery, however, there was a zone of pleomorphism having all the features of the so-called mixed tumors. It was obvious that an area of malignancy had developed in an originally benign growth.

CASE 2.—Mrs. M., aged 30 years, gave a history of pain around the right eye one and a half years before examination in May 1933, at the beginning of proptosis. The eye was removed in England, in December 1935, with most of the new growth. She was given 40,000 mg. hours of radium at Middlesex Hospital. Roentgen therapy was continued in Montreal.

In December 1939, papilledema (left eye), headaches and vomiting developed. An intracranial expanding lesion was present. The patient died December 23. There was no postmortem examination. The extension was apparently from the orbit.

The histologic sections showed cords and strands of small dark-staining cells. The abundant tissue between the epithelial clusters was collagenous and often hyaline, not pseudomyxomatous. In some areas large aggregations of the epithelial elements took on the appearance of developing embryonic glandular tissue with small acini in the masses. Invasion of surrounding fatty tissue had occurred. This growth showed less evidence of pleomorphism than the others and was definitely invasive. Its cylindromatous character was a distinctive feature. It was classified as an adenocarcinoma.

CASE 3.—Mr. E. C., aged 29 years, was first seen in June 1942 with a history of proptosis for three months and right-sided headache for five to six years. In July the mass was removed; it contained strumous material, seedlike in appearance. The patient made a good recovery. Seven months later there was recurrence in the same position. A lage part of an infiltrating mass was removed and exenteration was advised. The patient was seen by many consultants. Opinions varied from exenteration to roentgen and radium therapy. The patient refused exenteration. Extensive roentgen therapy was given. At the time of reporting the patient was still living, with no recurrence, but there was a mass below the tip of the mastoid. The patient refused biopsy.

Histologically the tumor was extremely pleomorphic with strands of epithelial cells, some showing squamous cell structure, a large amount of pseudomyxomatous tissue and areas of solid growth of closely packed branching cells which conformed to the basket cell derivatives described by Sheldon.[26] There were no areas simulating cartilage and no cylindromatous formation. This tumor was considered a pleomorphic adenoma.

COMMENT

From the classification of the original observers, reported by Warthin[27] and Lane, one might get the impression that the lacrimal gland is characterized by its ability to produce a large number of different types of growth. Actually, it is known that the opposite is the case and that aside from the lymphomatous infiltration in the Mikulicz syndrome and the occasional neoplastic curiosities all the tumors so differently designated are only variants of a single type ranging from benign to malignant pleomorphism. To this type the unsatisfactory term of "mixed tumors" is applied most frequently. No mention seems to have been made of the basket cells playing a part in the origin of these tumors, as occurs in the salivary glands and described by Sheldon. Case 3, herein reported, seems to be an example. If Sheldon's observations in tumors of the salivary glands are also true for tumors of the lacrimal gland, it might add to our knowledge of their development. In his conclusions, he stated that tumors of the salivary glands include cancerous and noncancerous neoplasms composed of one or two different types of neoplastic cells. Both types of cells are normally present in the salivary glands; one is represented by the secreting epithelium and the other by the basket cells. Some of the tumors arise from the epithelium, others from the epithelium and basket cells, which are true organized tumors, and a few arise from the basket cells alone. It seems to me that in future it would be helpful to try to classify tumors of the lacrimal glands along these lines.

In conclusion I should like to mention the views of Elton Mayo, who says that "knowledge of acquaintance" comes from direct experience of fact and situation, while "knowledge about" is the product of reflective and abstract thinking. I have tried in this presentation, as much as possible, to adhere to the expression of the former.

PRESENT STATUS OF THE PEPTIC ULCER PROBLEM

S. ALLEN WILKINSON, M.D.
Boston

Peptic ulcer is a classic example of a somatic disease which is greatly influenced by and possibly precipitated by psychic factors. All physicians have been impressed by the close relationship between nervousness, anxiety, worry or psychic trauma and the acute exacerbations of ulcer but we are apt to forget the admonition of Jordan[1] that there may be a somatopsychic as well as a psychosomatic interplay. The typical spring and fall exacerbations without obvious precipitating causes may result in worry, anxiety and nervous tension which in a sick person bring about family quarrels, business worries, fear of losing a job or other problems that are sure to aggravate any symptoms the unhappy victim may have.

The principal changes in the management of peptic ulcer in the last decade have not been primarily changes in diagnostic methods, but in the handling of the ulcer after the diagnosis is made. It is not the purpose of this paper to discuss the symptomatology or routine diagnostic methods that we all use, but rather to describe some of the problems in diagnosis and management.

To fail to find an ulcer when it is present deprives the patient of adequate treatment when he most needs it—in the early stages of the ulcer. Jordan[1] has properly said, "Clinical experience tends to show that peptic ulcer is too infrequently diagnosed rather than too frequently diagnosed." On the other hand, it is not proper to diagnose a peptic ulcer on the basis of history alone; the presence of the ulcer should be carefully verified by every means at our disposal. Incorrectly calling a functional digestive disturbance ulcer not only results in improper treatment, but it also wrongly labels the patient as having a disease that, later, may cause insurance companies or future employers to refuse to insure or to employ a person who is a good risk, to the serious detriment of the patient's economic status.

Not only should roentgenograms be employed in every case, but careful fluoroscopy is even more important. A small ulcer on the lesser curvature high in the media of the stomach would often be missed without careful fluoroscopic observation after a swallow ingestion of thick barium. Often by fluoroscopy antral spasm can be differentiated from a prepyloric malignant condition. A tiny, but persistent, deformity in the base of the duodenal cap can be verified by fluoroscopy when it can only be suspected from the roentgenograms. Palpation during fluoroscopy may be the only means of identifying a persistent fleck in the jejunum, the site of a jejunal ulcer. Such an ulcer may be tender, and the patient is often able to put his finger exactly over it at the time of the examination. The same finger point tenderness may be found present over an ulcer penetrating the posterior wall of the stomach or the duodenum, but this is not often the case.

An ulcer in the first portion of the duodenum beyond the duodenal cap can be recognized on the roentgenogram by a narrowing with a definite dilatation of the duodenum distal to this narrowing. At one time these areas were said to indicate duodenal spasm, but they represent actual ulcers. In fact, this narrowing may be all that can be found in the otherwise obscure bleeding ulcer. Roentgenograms of many of these patients following hemorrhage in the upper part of the gastrointestinal tract have been accompanied with a report of "normal stomach and duodenum," when the finding of the constriction might have given the clue to the actual location of the ulcer.

The laboratory data are helpful but never diagnostic. In particular too much reliance should not be placed on the presence or absence of gastric acid. While it is true that ulcer never occurs in the presence of true anacidity, it is also true that an occasional aspiration of gastric contents may fail to show acid even if an active ulcer is present. The old dictum that a malignant gastric condition produces achlorhydria is not always true. In 45 per cent of our cases of proved gastric carcinoma free acid was present in the stomach; hyperchlorhydria was present in 12 per cent.

Gastroscopy is now time tested and proved as a valuable adjunct to diagnosis, but its limitations are well known. By its use, one can often determine that an ulcerating lesion in the stomach is benign or malignant. However, the borderline cases may be just as difficult to determine from their gastroscopic appearance as from the roentgen appearance. In addition there are a number of blind spots where a fairly large lesion might be completely invisible. At the Lahey Clinic, my associates and I have found there has been a singular paucity of cases of gastritis. Some cases of gastritis, both atrophic and hypertrophic, are obvious, but my associates and I believe that in many of the borderline cases gastritis is not present, but simply day to day variations in a normal stomach. Gastroscopy will often show a small, incompletely healed gastric ulcer after the niche has completely disappeared on the roentgenograms.

MANAGEMENT OF PATIENTS WITH ULCER

Modifications of the old Sippy diet have proved most satisfactory, and we still prefer hourly feedings of milk and cream during a three week period of hospitalization. Neutralization of gastric acid is a prerequisite of good treatment. Diet alone will not adequately control the pain or heal the ulcer. Sippy powders are not used routinely, preference being given to aluminum hydroxide gel. We have had little success with the use of magnesium products. All of them, in doses adequate to control the acid, cause enough irritability and spasm of the colon to prevent their continued use.

Synthetic resins in finely powdered form theoretically offer the advantages of aluminum hydroxide without its disadvantage of aggravating constipation. Actually in about half of our cases in which it was the only neutralizing agent used the patients said that they felt no better or felt that their pain was increased.

Protein hydrolysates and amino acids have a place in the management of ulcer, but they do not contribute directly to the healing of the ulcer. The debilitated patient, the patient who has been on a deficient diet, the starved patient will all benefit from accessory feedings, including protein hydrolysates, just as they benefit from an extra allowance of vitamins. Many, and probably most, patients with ulcer, however, have been on adequate diets; they are not debilitated, and they have no protein deficiency. In this group accessory feedings of the portein hydrolysate type are costly, wasteful and unnecessary.

Enterogastrone is still in the experimental stage. Until a sufficient number of cases have been studied for a long enough time, it would be premature to try to judge or appraise its use in therapy. We have used enterogastrone in a small series, but are not yet ready to comment on our results. Bercovitz and his associates[2] recently reported on a series of intractable duodenal ulcers treated with an extract of pregnant mare's urine. It seems certain that some new and valuable form of hormonal treatment will emanate from the many investigations now under way at the instigation of the Committee on Peptic Ulcer fostered by the American Gastroenterological Association.

MANAGEMENT OF PATIENTS WITH GASTRIC ULCER

The medical management of patients with gastric ulcer has become a touchy problem. Some of our surgical colleagues have stated that all gastric ulcers should be treated surgically. They base their arguments on the following premises: (1) It is impossible to distinguish a benign from a malignant ulcer, clinically, roentgenographically or surgically; (2) the mortality of resection in skilled hands is less than 2 per cent; (3) recurrence of gastric or gastrojejunal ulcer after resection for a gastric ulcer is rare and practically does not occur, whereas after resection for duodenal ulcer both gastric and jejunal ulcer not infrequently recur.

The following comments oppose the foregoing arguments: 1. It is possible in most cases to differentiate clinically and roentgenographically between benign and malignant lesions. The percentage of malignant ulcers occurring on the lesser curvature of the mediums of the stomach in a young person (under 35) is extremely low. To sacrifice most of the stomach and permanently to change the digestive physiology in this large group to remove the rare malignant ulcer is an overuse of caution. The prepyloric ulcer in an older person may justifiably be regarded as a surgical problem from the start. In the younger group, however, frequent roentgen checkups, gastroscopy and careful checking of stools for occult blood will furnish satisfactory evidence that healing has taken place. If an ulcer fails to heal in three to four weeks, that should be considered sufficient evidence to justify operation. If the ulcer heals but recurs at any time in the future, operation should be performed immediately without further treatment. Every patient treated medically for ulcer should be followed carefully and checked by roentgenogram yearly or oftener for the rest of his life. 2. Even though the operative mortality rate in skilled hands is low, the morbidity rate after a subtotal gastric resection is still high: neither the mortality nor the morbidity rate is lower in less skilled hands, and all physicians see patients who never feel entirely well or normal after such operations. Jordan and Smith[3] have recently written that only in 3.2 per cent of their patients with ulcer selected for medical management did a malignant condition develop in a five year follow-up period.

MANAGEMENT OF PATIENTS WITH COMPLICATIONS OF ULCER

The most common complication of ulcer is obstruction. True obstruction is a surgical problem, but many ulcers produce a temporary blocking due to edema and spasm. The truly obstructing ulcer can be differentiated from the apparent one by a procedure[4] of draining the stomach through a nasal tube. Malted milk, amino acids and antacids are introduced hourly. The tube is clamped for half the time and allowed to drain into a bottle below the bed for the other half. This procedure will decompress a dilated stomach, will relieve pain promptly, and, if the cause of the obstruction is not due to scarring, the pylorus will relax in twenty-four to forty-eight hours, allowing food to pass through freely. Those patients do not require surgical management, and if they are properly treated the obstruction will not recur. If the obstruction persists more than seventy-two hours, operation is indicated. The ulcer may seem better temporarily, but obstruction returns as soon as the patient is up and about.

Hemorrhage, the next most common complication, is the easiest to diagnose and the most difficult to treat satisfactorily, either medically or surgically. The patient who has had two or more gross hemorrhages in our series has a small chance of dying but an unenviable chance of recurrent hemorrhage in spite of medical management (80 per cent) and a greater than suspected chance of recurrence after subtotal resection (29 per cent).[5]

Intractability is given as a reason for operation on ulcer, but the definition of an intractable ulcer varies from group to group and even from physician to physician. We have tried to make a distinction between the intractable ulcer and the intractable patient. It is often the latter, who refuses to stop smoking, who makes only desultory efforts to follow a diet, who cooperates poorly with any form of treatment, who helps to make up the large group of patients in whom treatment for ulcer has been a failure. This applies as well after operation as before.

VAGOTOMY VERSUS SUBTOTAL RESECTION

For years we have realized the shortcomings of subtotal resection as a treatment for ulcer. It does not guarantee freedom from recurrence; it is a major surgical procedure associated with some mortality and a larger morbidity; it is not always possible to remove the ulcer if it is a duodenal one. The operation imposes a major physiologic readjustment, and if it is not well done various unpleasant consequences ensue. If the anastomotic stoma is too big, the dumping syndrome is disabling and impossible to treat. If the stoma is too small, the gastric stump, which has little peristaltic activity remaining, empties too slowly. The patient complains of fulness and discomfort long after a small meal. As a result of inadequate intake, he loses weight and quickly loses the psychologic "lift" which first developed with the knowledge that at last he was getting rid of his ulcer. Postoperatively small intestinal adhesions may occur and cause partial obstruction. If recurrent jejunal ulcer occurs it presents both the patient and the surgeon with the vexing question, "Now what?"

With the advent of vagotomy it was hoped that many of these difficult problems would be solved. Theoretically the patient was left with an intact stomach and a desirable anacidity. Actually, the operation does relieve the pain of ulcer dramatically in 88 per cent of cases. Unfortunately the hoped for anacidity is difficult to attain. Postoperatively the gastric motility is so seriously impaired that most large groups have abandoned transthoracic vagotomy in favor of subdiaphragmatic vagotomy combined with gastroenterostomy. It is the belief of some thoracic surgeons that the ramifications of the vagus nerve in the chest are so diverse that it is next to impossible to get all the fibers. Dissections of cadavers have shown that in many instances major bundles of the vagus nerve enter the stomach through the esophageal muscles. It is now known that peptic ulcer does recur or that it may fail to heal following vagotomy. There are reports that ulcers have progressed until perforation has occurred, being completely without pain up to the moment of perforation.

At the Lahey Clinic over 90 vagotomies have been performed, 8 of which were transthoracic and 82, the remainder, subdiaphragmatic. In the majority of the subdiaphragmatic group, we have combined vagus section with subtotal gastrectomy. It is too soon to evaluate final results, but a recent review[6] of 62 of our cases of subtotal vagotomies combined with subtotal gastrectomy showed that the vagotomized patients had more complaints, more severe complaints, longer duration of complaints and just as many recurrent ulcers as those in a similar group who had undergone subtotal gastrectomy. It is for these reasons that we are skeptical of the permanent effects of vagotomy and are placing most of our reliance on subtotal gastrectomy. The one condition for which vagotomy alone might be considered is the recurrent jejunal ulcer following an adequately high subtotal gastric resection.

POSTOPERATIVE MANAGEMENT OF THE PATIENT WITH ULCER

Operation, whether it be gastroenterostomy, subtotal resection or vagotomy, does not relieve the internist of his responsibility. If we have had any one fact firmly impressed on us, it is the necessity for meticulous and long-continued postoperative management of the patient with ulcer. The tendency of the patient who has followed a diet and has taken antacids more or less faithfully for a long time and who at last undergoes an operation is to say to himself, "No more diets or medicine for me. My ulcer is gone and I can eat and drink what I like." Nothing could be more incorrect. If he is to prevent recurrent ulcer, it is the duty of the physician to impress on his patient the need for long-continued care and observation. The patient should be instructed that he must not smoke; that he must not drink, at least until it can be proved that he has permanent achlorhydria, and that he should follow a careful dietary regimen. If his investment of time, of money, of pain and discomfort to reach his present position is explained to him, he will usually cooperate intelligently and well. It is largely in the group who fail to take these lessons seriously that the recurrences will be found.

SUMMARY AND CONCLUSION

Peptic ulcer presents a diagnostic problem chiefly with regard to the detection of small or obscure duodenal lesions. The therapy of ulcer offers a challenge to the patience, the acumen and the ability of the practitioner and the surgeon alike. The preoperative preparation and the postoperative dietary management of patients with ulcer subjected to operation are equally important. It is not yet proper to speak of any patient who has had ulcer as cured.

ABSTRACT OF DISCUSSION

Dr. Wingate M. Johnson, Winston-Salem, N. C.: Speaking of the diagnosis of ulcer, I have been impressed with the fact that the average patient with ulcer has few other digestive complaints. He is not likely to say that he hurts all over or is flatulent after meals. It is generally just that clearcut picture of pain before meals, relieved by eating, with recurrences. The patients often say that alkalies will give relief. One other point which I have found mentioned by Bockus, and which my own experience confirms, is that a patient with duodenal ulcer, unless he has had a recent hemorrhage, is likely to have a blood cell count which is a little higher than average. Hemoglobin will go up to 16 or 17 Gm., and red cell counts are of 5,000,000 to 5,500,000; on the other hand, the patients with gastric ulcer are likely to have a rather low blood cell count. So far as treatment goes, I was pleased to find that Dr. Wilkinson is a little conservative. I have found little use so far for protein hydrolysates. I think that the average patient does rather well on the typical ulcer regimen. As a rule I do not put my patients in the hospital, but in the beginning use a bland diet, with alkalies to control the acidity. I agree with what Dr. Wilkinson said, that the intractable ulcer usually occurs in the intractable patient. I have had patients who got no relief from pain until they stopped smoking. Many of my patients are allowed to continue to smoke in moderation, but there are a few who have pain and do not get relief from it until they stop smoking. I was interested in what was said about vagotomy. Being a medical man, I am not as surgically minded as some of my colleagues.

Dr. S. Allen Wilkinson, Boston: Dr. Johnson is more lenient than I would be about smoking. I am firmly convinced that the proper treatment of ulcer includes complete stopping of smoking and that the difference, in most cases, between the patient who is well controlled medically and the patient who is partly controlled medically is whether he smokes or does not smoke.

STREPTOMYCIN AS ADJUNCT IN TREATMENT OF ACUTE PULMONARY TUBERCULOSIS

EDWIN R. LEVINE, M.D.
WILLIAM S. KLEIN, M.D.
and
ABEL FROMAN, M.D.
Chicago

With the introduction of streptomycin in the treatment of clinical tuberculosis in 1945 by Hinshaw and Feldman[1] there was hope, on the basis of experiments with animals, that this antibiotic would cause definite arrest or cure of pulmonary tuberculosis. It was not long before it became evident that in the type of tuberculosis most commonly seen in sanatoriums and hospitals, advanced tuberculosis with cavitation, treatment with streptomycin seemed to have at best only a temporary effect. It was noted that exudative tuberculosis would resolve and that early infiltrate might disappear, but that in general cavities remained and that the sputum cultures remained positive.[2] Fibrous elements in the lung, whether associated with cavities or not, were untouched by this drug.

The pathologic and physiologic aspects of the tuberculous lesion explain this type of reaction. Streptomycin reaches the diseased organs through the blood stream, and any lesion well supplied with blood has a chance to receive an adequate amount of streptomycin to produce the bacteriostatic effect. Such a pathologic condition is the acute inflammatory exudative type of disease.

That exudative areas are well supplied with blood is indicated clinically by symptoms caused by absorption of the toxic element from these areas into the blood stream, but well established cavities, as has been shown by Lipstein,[3] have little blood supply. The circulation around the cavity is barely enough to maintain viability of the tissue, and since well established cavities have a definite wall, there is little exchange between the circulating blood and the interior of the cavity. Clinically, this is evidenced by the absence of fever or toxic symptoms in the presence of a cavity unless some exudative elements exist elsewhere in the lung or the body. Since this is so, it would be expected that streptomycin or any other blood-borne medication would not have much effect on the tubercle bacilli residing within the cavity in the lung, although it might have a definite action on exudative areas in the lung of the same patient.

Another characteristic of streptomycin has also interfered with its general efficacy in pulmonary tuberculosis. This is the loss of effectiveness after a period of two to three months caused by resistance developed in the bacteria or the development of resistant strains.[4] For this reason it is generally considered that the peak of effectiveness is reached in sixty days and that little, if any, effect remains after one hundred and twenty days of treatment. However, it has been known for many years that tuberculosis does not heal in such a short period and that treatment must be continued over a period of many months or years to produce an adequate result. Consequently, any medicament the effectiveness of which is limited to a time so much shorter than the time required for treatment is not likely to be successful when used by itself.

All of these factors when added together seem to limit the use of streptomycin to early exudative tuberculosis without much cavitation. This would eliminate the most important group of patients requiring treatment—those with chronic pulmonary tuberculosis with well established cavities and acute tuberculosis with rapid caseation, cavity formation and pneumonic spread. The first group is customarily treated with bed rest, collapse therapy and operation. This treatment, which offers a high percentage of good results is, nonetheless, frequently interfered with by progressive disease and complications which nullify the effect of treatment. Acute tuberculosis cannot be directly attacked by operation or collapse therapy, but must be allowed to "cool off" with bed rest.[5] In a respectable percentage of cases this "cooling off" process never occurs, or only after the lung has been so seriously damaged that treatment is not possible.

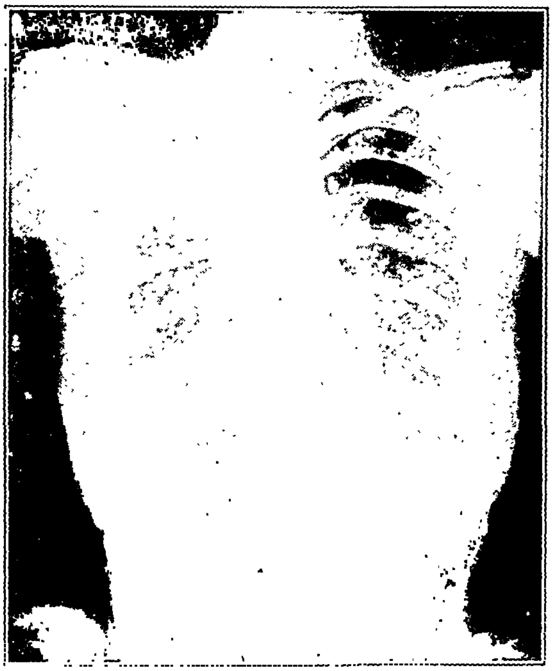

Fig. 1 (case 1).—Roentgenogram taken on admission, showing extensive caseous pneumonia on the upper lobe of the right lung and many bronchopneumonic areas in the lower lobes. On the left side a cavity may be seen underlying the third rib anteriorly, with extensive bronchopneumonic changes below.

It has been adequately demonstrated by Hinshaw and Feldman[6] that streptomycin will cause resolution of exudative elements and diminish toxicity and that during the first sixty days, at least, of treatment will prevent the extension of the disease. These characteristics of streptomycin cause just the change in an active tuberculous disease that is required to insure safe and successful collapse therapy.

It was for this reason that streptomycin was used in these two types of disease—not solely but as an adjunct to make possible or to render safe our estab-

lished methods of treatment. It was felt that a plan of treatment should be made in each case and streptomycin fitted into that plan at the place where it would be most effective, with the time limitation of its effectiveness borne in mind. Such a program was used in the treatment of 26 patients with far advanced bilateral tuberculosis, whose disease was too acute or too extensive for routine collapse or surgical measures. The following cases indicate how this program worked out.

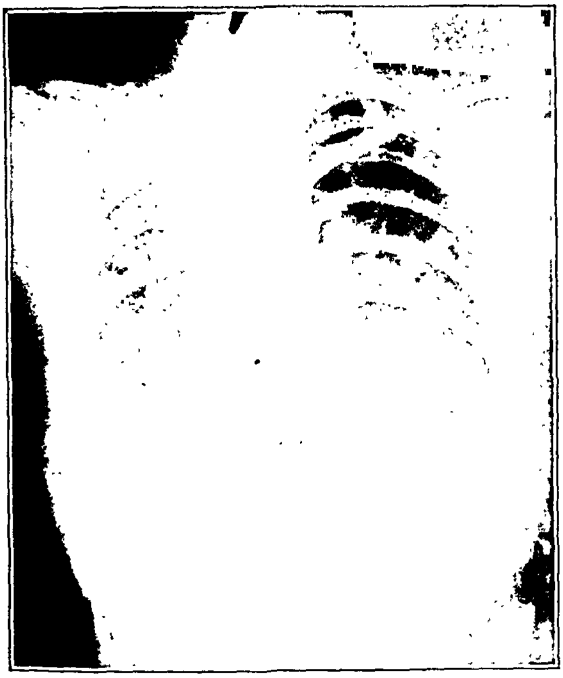

Fig. 2 (case 1).—Roentgenogram showing further destruction in the upper lobe of the right lung and extension of the disease. A pneumothorax was done on the left side.

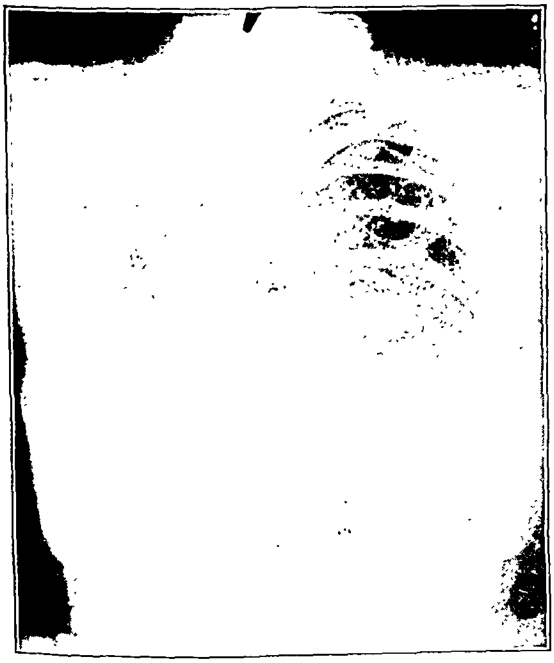

Fig. 3 (case 1).—Roentgenogram taken shortly after administration of streptomycin, showing little improvement, with the cavity still present on the left side and the appearance of tuberculous effusion.

REPORT OF CASES

Case 1.—M. K., a 21 year old white woman was admitted to Winfield Hospital on Sept. 24, 1946, with a three month history of tuberculosis. On admission the patient was acutely ill and had a spiking temperature with daily variation between 100 and 103 F., and a pulse rate of 100 to 120. The roentgenogram (fig. 1) showed extensive far-advanced bilateral disease, with almost complete involvement of the right lung, multiple cavitation in the upper part of the right lung and tuberculous pneumonia below. On the left, the apex was involved with cavitation in the middle part of the lung.

Pneumothorax was attempted, without success, and bed rest was continued, with the patient maintaining a steady downhill course. At this time her condition was toxic, and there was evidence of tuberculous enteritis, tuberculous bronchitis and laryngitis. On October 25, a diagnostic pneumothorax was done on the left side.

Her condition became so poor that it was highly questionable whether any treatment would be able to stop the course of this disease. Nevertheless, it was our feeling that, if the toxicity of the disease were decreased and its progression stopped, there might be some chance of applying surgical collapse to the right lung. The major lesion was on the right side, occupying almost the entire area of the lung. There was a lesion occupying the apex and the middle part of the left lung, and a diagnostic pneumothorax was done to determine whether cavitation was present and whether pneumothorax could offer some control of this lesion. Collapse was successful and showed a small cavity in the middle part of the lung.

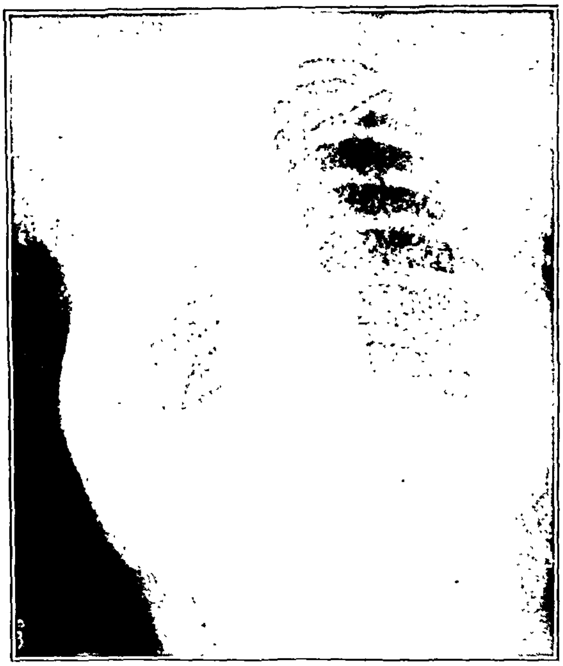

Fig. 4 (case 1).—Roentgenogram taken eight weeks after thoracoplasty and after pneumothorax of the left lung had been abandoned, showing the lung to be clear. There was no further extension of the disease on the right, and the general condition of the patient was good.

This collapse was maintained, and treatment with streptomycin was started on November 6, 2 Gm. a day. At this time the temperature reached a peak of 102 F. every day; the pulse rate varied between 120 and 140, and the patient was extremely sick and her condition toxic (fig. 2). Little improvement was noted after four weeks of treatment, although the roentgenogram did seem to show some clearing of the acute pneumonic areas in the right lung. By December 20, five weeks after the institution of streptomycin therapy, the temperature had dropped as low as 101 F. daily, the pulse rate varied from 105 to 120 and the patient showed sufficient general improvement to justify surgical treatment (fig. 3).

Thoracoplasty was done in three stages, the last stage being done on Jan. 27, 1947. With each stage of thoracoplasty there was decided improvement in the condition of the patient, and at no time was there any evidence of exacerbation of the disease or extension of this process. Pneumothorax was discontinued on January 15, after the second stage, because of the extreme dyspnea of the patient. It was hoped that, since the cavity had already closed with streptomycin therapy, it might remain obliterated. With completion of surgical treatment, the reaction of the sputum became negative, and it remained so. Eight weeks after the first stage of operation the patient was allowed out of bed, and a program of gradual physical rehabilitation was instituted (fig. 4). The patient responded well to this treatment and was discharged six months later with a diagnosis of arrested disease. She has remained well since and on a program of normal activity.

Comment.—This represents a type of case in which the disease is not amenable to treatment in ordinary circumstances. This was active progressive caseous pneumonia in a young girl, and as indicated, there was no noticeable improvement with a reasonable period of complete bed rest. However, the loss of toxicity and resolution of exudative areas, which accompanied the administration of streptomycin, and the relative safety from postoperative extension of the disease made it possible for us to perform an operation on this patient, which controlled the active pathologic condition. The plan in this case was to administer streptomycin until the toxicity was sufficiently diminished and the condition of the patient sufficiently improved to make surgical treatment a justifiable hazard and to continue treatment with streptomycin in the postoperative period for fully four months.

The result in this patient justified our expectations. First, there was a progressive decrease in the toxicity of the disease, with a lowering of temperature and improvement in the general condition of the patient Secondly, there was extensive operation on an actively tuberculous chest, without any spread or extension of the disease and without any complication referable to the tuberculosis. The decided reversal in the course of the disease from a steadily accelerating downhill course to an increasingly improved status was dramatic in this case.

Case 2.—M. B., a 24 year old white woman, was admitted on Oct. 31, 1946, with a seven month history of cough and pain in the left side of the chest. The reaction of the sputum was highly positive, and a large cavity was visualized in the upper lobe of the left lung, with a shadow off the left cardiac border which could be demonstrated to be encapsulated, interlobar effusion.

Pneumothorax was induced on the left side November 11 as the procedure of choice. However, the collapse was contraselective, the diseased area of the lung being completely adherent, and the cavity remained open. On December 2, the patient complained of sticking pain in the right side of the chest posteriorly, and roentgenographic examination at that time revealed a fresh pneumonic area in the base of the upper lobe of the right lung. On serial examinations this area in the right lung seemed to be increasing in size, showing suspicious signs of excavation, and there appeared to be extension into the lower lobe of the left lung. Because of the completely ineffective pneumothorax on the left, surgical treatment was considered indicated. However, the acute nature of the disease and the progressive lesion in the right lung gave evidence that extension could be expected during the surgical period with a probable unfortunate result.

Treatment with streptomycin, 2 Gm. daily, was started on December 20, at which time the patient had a temperature of 101 F. daily, and a two stage thoracoplasty was performed in January 1947, at which time the temperature was normal and resolution had occurred on the right side. The streptomycin therapy was continued through the postoperative period until February 13.

After operation the patient's cough and need for expectoration disappeared completely, and the reactions of the gastric washings had remained negative from February 24 to the date of writing.

Serial roentgenograms showed progressive resolution on the right side, and at the time of the last examination there were only a few fibrous strands in the area of the previously acute caseous tuberculosis. Her sedimentation rate was 6 cc. (contrasted with 22 cc. preoperatively); her temperature and pulse rate were normal, and she was discharged from the hospital, with full physical activity permitted, on June 20.

Comment.—In this patient, one method of treatment was unsuccessful and acute caseous pneumonia developed while bed rest was still part of the regimen. The condition in this patient was not amenable to ordinary treatment, and since the disease extended with bed rest, there was no hope that further bed rest would cause resolution. The plan here was to use streptomycin until there was sufficient resolution, particularly in the contralateral lung, to justify the risk of operation. Thoracoplasty was the method of controlling the disease. Streptomycin therapy was continued postoperatively for a full four month course.

It was noticeable in this case that the toxic symptoms subsided rapidly and that the downhill course of the patient was sharply arrested. The steady improvement of the acute lesion in the contralateral lung right through the surgical episodes is contrary to the customary experience in such cases without streptomycin therapy.

Case 3.—The onset of illness occurred early in February 1946, and the patient (W. G.) was admitted to hospital on February 26. There he remained, with complete bed rest, until he was admitted to Winfield Hospital on July 24. On admission he had a high spiking temperature, ranging from 99 to 103.8 F., and his general condition was poor. The patient was extremely weak and thin. A roentgenogram showed extensive caseous tuberculosis, involving almost all of the left lung, with extensive cavitation and multiple areas of tuberculous exudation in the right lung. Considering the history of six months of absolute bed rest and the poor condition of the patient, further rest was not considered advisable. Because the disease was spreading consistently, artificial pneumothorax was started August 5, on the left side, although it was realized that chances of complications were great. A roentgenogram taken after induction of pneumothorax showed almost complete shelling out of the left lung, with resulting extensive excavation. There was some decrease in temperature, so that it remained consistently below 101 F. Adhesions were present opposite the large cavity, with the cavity actually entering the adhesions. Pneumonolysis was thus considered out of the question, and a left phrenic crush was done. It was felt that the only type of treatment to offer a chance of cure was a pneumonectomy, but the condition of the patient was much too poor to consider any major surgical procedure.

On Jan. 8, 1947, the temperature became elevated, spiking up to 103 F. daily, and the patient began to expectorate larger amounts; a large amount of fluid was present in the chest. Expectoration of dye injected into the pleural space showed the presence of a bronchopleural fistula. There was extensive tuberculous pneumonia in the lower third of the right side of the chest. The condition of the patient deteriorated to the point where it was felt that he could not survive much longer. Streptomycin therapy was started January 13, because of the bronchopleural fistula and contralateral tuberculous pneumonia. It was felt that if the pneumonia in the right lung would improve somewhat, it might be possible to operate on the left. There was decided improvement and resolution of the pneumonia on the left side, and a thoracotomy was done with insertion of a tube in February. Following this, the patient improved, and there was a decided decrease in toxicity. The temperature remained irregular; fever was low grade, never exceeding 101 F.

On April 13, a first stage thoracoplasty was done; the second stage was done on April 23 and the third on May 8. The patient had an uneventful recovery from each stage of operation, although the last was extensive, with removal of part of the parietal pleura. He returned to Winfield Hospital May 24, and his temperature remained consistently below 99 F., his general condition being much improved. He continued to gain weight and strength, was allowed out of bed eight weeks after the first stage of operation and continued to improve. The right lung, in which acute tuberculous pneumonia had occurred, showed complete resolution, with only a few fibrous strands remaining at the site of the pathologic condition.

This patient's condition continued good. He gained 34 pounds (15 Kg.), the sputum cultures remained negative for tubercle bacilli and under a program of rehabilitation he returned to a normal status. After one year of observation and rehabilitation, he was discharged to continue his training as watchmaker and had remained well as of the time of writing.

Comment.—The disease in this case got completely out of hand. There was no control of the extensive lesion in the left lung. There was acute tuberculous empyema with bronchopleural fistula and subsequent extensive tuberculous pneumonia on the other side. The reduction of toxicity by the use of streptomycin plus the resolution of the pneumonic disease on the right side made it possible to do the extensive operation on the left. The plan here was to use streptomycin until the toxicity was sufficiently reduced to risk surgical treatment in small stages with the use of streptomycin, with the hope thereby of avoiding further extension to the right side from the bronchopleural fistula and the cavity until such time as these two areas were brought under control by the surgical procedure. Streptomycin therapy was continued for five months.

In this case the activity was such that there was no reason to believe that streptomycin would effect control of the disease. In fact, we do not believe that streptomycin controlled the tuberculosis in this case. Actually, what was accomplished was the diminution of toxicity, so that the patient could be built up to withstand extensive surgical treatment. During the same period decided resolution of the extensive tuberculous pneumonia occurred, and there was no further extension, although the bronchopleural fistula remained open.

These three factors created a clinical situation comparable to that of a patient with a disease of much lower toxicity that had not spread and without bronchopleural fistula. Such a condition is amenable to surgical treatment, which was possible in this case. The patient withstood the operation well and continued his improvement postoperatively, even after streptomycin therapy was stopped.

CASE 4.—A. D., a white woman aged 30, was admitted to Winfield Hospital Sept. 30, 1946. The onset of illness was five months before admission, and the patient had a regimen of complete bed rest for three months before admission to the hospital. Examination showed an acutely sick woman, with extensive bilateral far advanced tuberculosis and a giant cavity in and multiple cavitation of the upper lobe of the left lung and multiple cavitation of the upper lobe of the right lung, with areas of tuberculous pneumonia below. She showed a spiking temperature, varying daily from 99 to 102 F. and a pulse rate varying from 100 to 120. There were associated tuberculous enteritis, laryngitis and bronchitis.

Because of the progressive deterioration in the patient's condition, artificial pneumothorax was instituted on the left side on October 7, with the hope of controlling some of the disease. The cavity did not close, and a broad adhesion was seen extending to the thoracic wall at the site of the cavity in the lower lobe. The acuteness of the lesion and the fact that the cavity was so close to the adhesion made pneumonolysis an extremely dangerous procedure, and the risk was considered too great to justify the operation.

On Jan. 1, 1947, streptomycin therapy was started, with the feeling that if the toxicity of the disease decreased enough it might be worth the risk of cutting this large adhesion. If this procedure resulted in closure of the cavity of the lower lobe, *it might be possible to induce some type of collapse on the right* side. There was some improvement about two weeks following the institution of streptomycin therapy. One month after streptomycin therapy had been started the temperature remained below 100 F. Pneumonolysis was done, without any complication, on April 1. However, the cavity did not close. On April 10, there was some increase in temperature, and a week later the patient began to show daily increase, the temperature reaching as high as 104 F. This was not thought to be due to the pneumonolysis, since there was no fluid or other evidence of pleural inflammation, and a roentgenogram showed some new pathologic changes on the right, the side opposite to that operated on.

Streptomycin therapy was continued for two months longer, totaling five months of treatment. During the latter two months, however, the temperature continued elevated. Laryngeal symptoms and evidence of lesion reappeared, and the condition of the patient deteriorated. Also, during this period there was increased activity of the lesion on the right side, with many new areas of tuberculous pneumonia and additional cavities in the upper lobe.

Comment.—This was a case that did not appear to differ from some of our cases in which treatment had been successful. There was, however, one major difference. At no time did the clinical status change sufficiently to justify enough collapse or enough surgical treatment to control the tuberculosis. The changes shown by this patient, in regard to decrease in toxicity, improvement in general condition and resolution of exudative elements, were equal to those in our cases in which operation was employed. However, the location of the pathologic condition, that is to say, the fact that there was almost complete destruction of the left lung and extensive cavitation in the upper lobe of the right lung, made surgical treatment impossible, because of the lack of respiratory reserve.

Consequently, we observed that after one hundred days our patient began to show increased symptoms, rise in temperature and recurrence of tuberculous bronchitis and laryngitis, which had previously been much improved. Following this, there was extension of the tuberculous disease on the right side and a continued downhill course. We feel that such observations indicate that the control offered by streptomycin therapy is limited as to degree and as to time and that whatever definite method of controlling tuberculosis is to be used, it must be used within the limited period. Furthermore, whatever surgical treatment is indicated, it can be done only when the control offered by streptomycin therapy brings the patient within that limitation.

DOSAGE

The dose used in this series of cases varied from 2 Gm. in the beginning to a present accepted dose of 0.5 to 1 Gm. daily. At the beginning of this work streptomycin was administered in eight divided doses in twenty-four hours. The process changed as information on the drug increased, and we are now administering the aforementioned dose in a single daily injection. We have found that in most cases 0.5 Gm. daily is an adequate amount. This is similar to the experience of other workers in the field.[7]

[7] Pfuetze, K. H., and William, A. M.: Present Status of Streptomycin in Tuberculosis, Dis. of Chest **14**: 446, 1948; Report of Committee on Chemotherapy and Antibiotics, American College of Chest Physicians, ibid. **14**: 766, 1948.

COMPLICATIONS

No serious complications were noted in the entire series. It was noticed, furthermore, that the diminution of the dosage to 1 Gm. of streptomycin a day was associated with a decided decrease in the number of complicating symptoms. Dizziness was the commonest complication occurring in the series, associated with permanent vestibular changes in only 1 patient. Numbness around the mouth, nausea and itching of the skin also occurred. Since for all of these patients the expected benefit from streptomycin therapy outweighed any except the most dangerous of complications, we were not deterred from its use by the untoward symptoms that occurred. Even if a larger percentage had shown permanent loss of equilibrium, we do not believe that this would contraindicate the use of streptomycin in a patient whose prognosis is questionable without it. There was no loss of vision and no deafness or other permanent toxic manifestations.

RESULTS

There were 26 patients in this group. One of the criteria used in the selection of cases was that the opinion of the entire staff must be that collapse therapy or surgical measures were imperative to effect a successful result and that bed rest alone would not do this. Furthermore, there was general agreement in each of these cases between the medical and surgical departments that surgical collapse was extremely hazardous or impossible at the time streptomycin therapy was started.

Of the 26 patients, there was successful collapse or operation in 24. In 1 of the 24, for whom a pneumonectomy had been done, there developed a bronchial lesion and exudative disease in the remaining lung within six months following operation. One patient did not improve sufficiently to permit any surgical procedure, and after one hundred days the original symptoms returned, with a downhill course. One patient recovered sufficiently to justify surgical collapse, but died in the postoperative period from atypical pneumonia, which was demonstrated by autopsy.

When we consider these results with the complications that occurred, we feel that in no case were the complications sufficiently severe to vitiate the beneficial effects of streptomycin therapy. Another interesting study is of the result of treatment on the pathologic changes in the lung opposite to that operated on or collapsed. In every case there was decided improvement. In 7 of the cases there was definite roentgenographic evidence of real fibrosis, representing an advanced healing stage of the tuberculous disease in that lung. Demonstrable cavities closed in 2 cases, and there was resolution of the exudative tuberculosis in every case in which such disease was present. It is noteworthy that in the 2 cases in which the contralateral lung showed extensive cavitation the cavitation remained unchanged during treatment with streptomycin. In 1 such case the disease extended as previously noted, and in the other it was possible to use bilateral pneumothorax to effect bilateral control. Treatment was given as follows:

Thoracoplasty	11 cases
Pneumothorax	9 cases
Pneumonolysis	3 cases
Pneumonectomy	3 cases

COMMENT

In this series of cases streptomycin was used as an instrument, or as an adjunct, and not for complete cure. Used thus it has an effectiveness and value unequalled by any other type of medicament. However, it is worth emphasizing again that in patients with advanced caseous tuberculosis, who make up such a large proportion of the patients treated, streptomycin therapy alone does not affect the total result, nor is it possible to apply collapse and surgical procedures in all of these patients without such aid. The combination of streptomycin with collapse therapy or other operation was the important factor.

In this connection, it is noted that the time schedule seems to play a greater part in the treatment in this type of case. One can never be sure, when treatment is started in extensive tuberculosis, just how soon the disease will be definitely controlled. Consequently, the margin of safety, representing the time when streptomycin therapy will still be effective, should be rather large, so that, if operations are delayed, if more stages are required than were anticipated or if the cavity does not collapse within the anticipated time, the effectiveness of streptomycin therapy will remain until control is assured. For this reason treatment with streptomycin should not be started in this type of case until a complete plan of treatment has been worked out. If streptomycin is used too early, there is the ever present danger that at the time when its effectiveness is most necessary that effectiveness will be greatly diminished.

In general, a period of one to two weeks of streptomycin therapy should be sufficient before operation, except for the patients who are so weak and toxic that, in addition to a degree of control, it is necessary to rebuild the patient before surgical intervention is attempted. Such a situation should be avoided, if at all possible, since the period of rebuilding may be longer than the effective period of streptomycin therapy.

We feel, furthermore, that there is a great danger inherent in the indiscriminate use of streptomycin for pulmonary tuberculosis. A trial period, to see whether cavities will close or lesions come under control, is tempting to the clinician and certainly desirable from the standpoint of the patient. However, when one considers that such a trial period must cover a minimum of sixty days, one realizes that if it should fail the opportunity to use the protective and deterrent action of streptomycin during the period of operation and collapse, when extension of the disease is likeliest to occur, would be lost. Furthermore, if there should be temporary improvement, followed months later by reactivation of the tuberculosis, there is always the danger that the resistance to streptomycin will remain. There is as yet insufficient evidence to make any statement regarding the return of sensitivity or the duration of resistance.

Consequently, it would seem that streptomycin should be used only when there are definite indications, for a definite purpose and as a part of a completely formulated plan. It should never be used in a therapeutic test or during a period of observation of a patient for whom other treatment may be required.

SUMMARY AND CONCLUSIONS

Streptomycin is not effective in the treatment of chronic pulmonary tuberculosis with well established cavities. However, for this condition, as well as for acute tuberculosis with rapid caseation, cavitation and pneumonic spread, streptomycin was used as an adjunct to the regular and accepted methods of collapse therapy and excision. We have observed it to be the most valuable single medicament known to us.

To date, the disease in 19 patients, all of whom presented lesions which were impossible to treat or could be treated only with great risk, has been controlled successfully by this means. Apparently streptomycin therapy caused a decided diminution of toxic symptoms, inhibited further spread of the disease and aided in the resolution of recent infiltrations. This had the effect, in general, of altering a lesion so that it could be successfully treated by standard methods.

We feel that in pulmonary tuberculosis, with the exception of early simple exudative disease, streptomycin therapy should not be instituted until a complete plan for the treatment of the patient has been formulated. There is great danger in using streptomycin too early, in that its effectiveness may be lost by the time collapse therapy or other surgical procedure is needed, and the assistance thus rendered would be wasted.

It has been noted that in these two types of disease, streptomycin therapy, although not successful in producing a cure, had certain definite effects. There was decrease in temperature and in other toxic symptoms, and no further spread of the disease occurred while recent infiltrations became resolved. Considered in the light of collapse therapy, this means that the factors which prevent treatment or interfere with successful completion are eliminated by the use of streptomycin.

REFUGEE PHYSICIANS IN THE U. S. ZONE OF GERMANY AND THE MUNICH MEDICAL TEACHING MISSION OF 1948

LOUIS FINDLAY, M.B., Ch.B.
Munich, Germany
and
ALEX. M. BURGESS, M.D.
Providence, R. I.

PART I

Throughout Germany today, in former SS *Kasernen*, temporary wooden barracks, shell-pocked apartment houses, small housing units, former slave labor camps and exschoolhouses and monasteries, live the United Nations displaced persons.

There are 280,000 of them receiving care and maintenance from the International Refugee Organization in the United States Zone of Germany, and another 160,000 existing precariously on the German economy but potentially eligible for legal, repatriation or resettlement assistance from the International Refugee Organization.

The displaced persons or refugees represent the remainder of the forced laborers and concentration camp victims of the Nazis, as well as those who fled from their homelands in fear of political or religious persecution. They include also the children kidnapped under a Germanization program, thousands of whom have since been traced to the homes or institutions to which they had been given as booty.

When the International Refugee Organization began operation in July 1947, it assumed responsibility for the care in assembly centers of refugees and displaced persons.

During the last twelve months, 16,000 refugees have left the camps to return home and 72,275 have departed for resettlement in one of fifty-one countries which have offered to receive them.

Some of the countries have opened their doors only a crack, admitting only five or six new settlers, usually relatives of their citizens. Others, like Great Britain, Canada, Belgium and South American countries, have taken thousands of new settlers, primarily on employment schemes and chiefly from among the single men and women or married couples without families.

Most encouraging news to displaced persons still in camps was the passage of the D. P. Act of 1948, which would permit 205,000 of them to go to the United States during a two year period, a number of whom will be doctors, dentists and nurses.

However, those still awaiting a passport to somewhere have taken a positive part in improving their lot. Instead of sitting on their suitcases in the 46 square feet of space allotted each displaced person, they have assumed the task of self government in their communities; they have enrolled in vocational training courses; they publish newspapers and magazines (of which there are seventy-two in the United States Zone), they supply the skills needed by the community—its doctors, nurses, dentists, teachers, engineers, lawyers, camp police, maintenance workers, seamstresses.

When the International Refugee Organization assumed responsibility for the camps, there were 2,500 international recruited employees administering approximately the same number of displaced persons, who are now supervised by 750 International Refugee Organization employees. The difference was made possible by the increased emphasis placed on assigning to displaced persons the responsibilities for running their own affairs.

In the medical program for the refugee population the displaced persons have also assumed a large part of organizing their own affairs and are now largely responsible for much of the medical organization and services.

In the United States Zone of Germany the international staff of medical officers who supervise the public health program in the displaced persons' camps has been greatly reduced in the past year with consequent responsibilities devolving on physicians and nurses who are displaced persons. There remains only a small supervisory staff of International Refugee Organization medical officers who have over-all responsibility for the medical and hospital services. That the health records of the displaced persons remain satisfactory and, in fact, progressively improve is a particular tribute to the large number of D. P. doctors and other medical personnel who staff the International Refugee Organization hospitals and camp clinics. Generally speaking, it can be said that the health status of the displaced persons is good, and this is confirmed by all available statistics on hospitalization rates, communicable diseases and infant mortality rates. The nutritional status in general compares favorably with that of most Western European countries today.

The population of displaced persons has available to it an extensive hospital and camp medical service largely maintained by the loyal work of the displaced persons medical personnel of all categories. In the United States Zone of Germany there are 2,733 hospital beds for tuberculous patients and 4,616 hospital beds for general patients. All these hospital beds are in hospitals operated by the International Refugee Organization, and in addition the International Refugee Organization has

---

Part I was written by Dr. Findlay, chief medical officer, International Refugee Organization, United States Zone, Germany, and part II by Dr. Burgess, chairman of the Medical Teaching Mission.

contracted with many German hospitals for the additional care of displaced persons.

The average displaced person living in a large camp has immediately available to him, inside his own community, a full range of medical clinics, staffed for the most part by specialists in their particular fields of medicine. The camp polyclinic usually centers round the camp hospital or infirmary and comprises a camp pharmacy, general medical clinic, special clinics for gynecology, children's diseases, venereal diseases and tuberculosis. In addition there is usually a well-baby clinic, infants' milk center, school clinic and school feeding center. It will be seen, therefore, that the displaced person has available to him a more easily accessible and more extensive medical service than he has probably ever experienced before. Tuberculosis is subject to special control measures, and a network of tuberculosis control clinics is in operation throughout the United States Zone of Germany, staffed by specialists in tuberculosis, both displaced persons and German. In conjunction with these control clinics a mass roentgen examination is at present in progress and a mass BCG vaccination program was completed during the summer of 1948. A rehabilitation program, both for selected persons with tuberculosis and for other disabled persons, has been started and will be extended during the coming six months. The incidence of communicable diseases among the displaced persons is remarkably low and immunization precautions and spraying with DDT (dichlorodiphenyltrichloroethane) are routine. During the summer of 1948 an epidemic of typhoid ocurred in one locality in Bavaria because of an infected water main which supplied a displaced persons' community as well as the neighboring German town. In the German community there occurred 1,018 cases of typhoid with 83 deaths, while in the displaced persons' camp concerned there were 14 cases of very mild typhoid and no deaths.

MEDICAL POPULATION

During 1948 a special board was constituted by the International Refugee Organization to establish and register the medical credentials of displaced and refugee physicians and other medical personnel. A special board was established for the same purpose of registering qualified nurses and midwives: similar boards constituted by the International Refugee Organization were established in other zones of Germany and other areas of its operation. The special qualifications (medical) screening board established in the United States Zone of Germany consisted of five permanent members and a number of consultant members. The members of the board were carefully selected by the International Refugee Organization on account of their nationality and knowledge of medical schools of Eastern Europe. The president of the board is Professor Jenö Kramar, a Hungarian professor and former Rockefeller scholar who is referred to again in the second part of this paper. The board and consultants are all themselves displaced persons. They were charged with the responsibility of interviewing all medical and dental personnel and registering their qualifications. In a large number of cases the doctors among the displaced persons had managed to retain their original diplomas or documents of medical qualification, and in these cases the work of the board was relatively simple, although in all cases identity and credentials were scrupulously checked. In many other cases, however, the doctor, during his years of hardship, often in a concentration camp, had lost all trace of his original documents. Such cases were fully investigated by the board. Photostatic copies or certificates of qualification could sometimes be obtained from the original medical school, and many other means were followed by the board in establishing the medical register. It can be stated with the fullest confidence that the work of this board has been done according to the highest concepts of medical ethics, and that the medical register of the International Refugee Organization is a true reflection of the medical qualifications of the displaced persons registered. The International Refugee Organization is issuing to each person registered a certificate stating the particulars of his original medical qualifications. As a result of this registration there are at the present time in the United States Zone of Germany 1,461 registered refugee physicians, of whom 901 are general practitioners.

It will be seen, therefore, that the resettlement of these refugee physicians, many of whom are men of high medical caliber, is a major problem facing the International Refugee Organization today. At present many of these doctors are filling their time by caring for the medical requirements of their own groups of displaced persons. Others are unemployed and longing for the day when they can again put their knowledge and skills to the benefit of communities. Others, already frustrated by their years in concentration camps during the war or in displaced persons' camps since their liberation, have accepted work opportunities as laborers in countries offering resettlement. There is, without a doubt, a large number of well trained and widely experienced physicians anxiously awaiting the opportunity to give a wider service.

In the field of medical education it has not been possible to do a great deal since the end of World War II, although much excellent work has been done in nursing education. All graduate nurses among the displaced persons have benefited by refresher courses. In the summer of 1948, however, it has proved possible for the International Refugee Organization to organize, with the assistance of voluntary agencies, two postgraduate medical refresher courses in a finely established International Refugee Organization hospital in Munich. The International Refugee Organization approached the Unitarian Services Committee in New York, a committee with extensive experience in organizing medical postgraduate courses in Europe, with a view to the establishment of such a course for physicians among displaced persons. The Unitarian Services Committee willingly accepted this proposal and agreed to sponsor the arrangements for the course in the United States.

Dr. Alex. M. Burgess, who contributes the second part of this paper, was appointed as chairman of this medical teaching mission. Dr. Burgess, physician in chief at the Rhode Island Hospital until January 1948 and professor of health and hygiene at Brown University, had as his colleagues Dr. Peter Chase, retired senior surgeon of Rhode Island Hospital, Dr. Benjamin Kramer, associate professor of pediatrics, Long Island Medical College, Dr. Sidney Greenberg, instructor in medicine at Cornell Medical School, and Dr. Robert Alter, recently appointed professor of obstetrics at the American University, Beirut, Lebanon.

The medical specialists selected as students for these postgraduate courses were selected by the International Refugee Organization medical officers and by the medical director of the American Joint Distribution Committee, one of the voluntary agencies supporting the International Refugee Organization in this teaching project.

* * * * * *

PART II

With the background of information that has been presented by Dr. Findlay it remains to describe the actual operation of the mission and as far as is possible at this time to evaluate the results that have been achieved. The original plan of the course has in the main been followed. Certain deviations were made in the first of the four week sessions because of the death of a relative of one of the members of the mission which necessitated his return to America. Furthermore, about three quarters of the teaching material, slides, charts and so forth did not arrive until the course had been in operation for two and a half weeks. These difficulties were overcome in the following manner.

Professor Jenö Kramar, himself a displaced person, conducted the work in pediatrics for the first two weeks in the place of Dr. Benjamin Kramer. He had formerly been professor of pediatrics at Szegad in Hungary, as well as dean and rector of the university. He was familiar with medical literature through 1943. His teaching laid the ground work for the presentations of newer material made by Dr. Kramer on his return at the beginning of the third week.

In place of the slides the staff was forced to use various illustrations from medical books and periodicals or to improvise charts, but these were exhibited successfully by the use of an excellent epidiascope, which the mission was able to secure from Professor Singer, Director of the department of pathology of the hospital.

The routine work in the course consisted of ward rounds or clinics from 9 to 10:30 a. m. and "lecture periods" at 11:00 a. m., 2 p. m. and 3:30 p. m. These "lectures" were presentations of various topics, each by a member of the mission, followed by a discussion period of varying length. In some instances they assumed the form of panel discussions in which various aspects of a subject were presented, each by a different person, and these were followed by a general question and answer period. For example, thyroid disease was taken up by the internist, then by the pediatrician, the gynecologist and the surgeon. The regular work of the day ended at 5 p. m., and on three evenings a week a medical motion picture, followed by another which was nonmedical, was exhibited for the entertainment of those who cared to attend. This type of daily program was carried on five days a week, with Saturday and Sunday free to allow those enrolled in the course to have time for study and recreation.

A medical library was established through funds furnished by the International Refugee Organization, with a D. P. physician on duty at appropriate times as librarian. In addition to this every physician enrolled received one textbook in English as a permanent possession, the gift of the International Refugee Organization. The library contained volumes written in English and purchased in America, as well as some in German which were obtained in Switzerland.

Certain additional features were added to the original plan of work. A weekly conference on pathology with the demonstration of postmortem material, both gross and microscopic, was held by Professor Singer. These were very instructive and valuable exercises and in many instances were related directly to the subject matter which had been taken up in the "lecture periods."

Besides these demonstrations, visits to various clinics were made by the groups interested in each of the specialties with which the mission was concerned. For example, the internists visited the International Refugee Organization sanatorium for treatment of tuberculosis at Gauting, where an excellent clinical meeting was held for their benefit, and the latest methods were demonstrated by staff members most of whom were themselves displaced persons. The surgical group made visits to an orthopedic clinic and the U. S. Army 98th General Hospital, and the pediatric group attended two pediatric clinics in the city of Munich. In the same way those interested in obstetrics and gynecology went to the University Frauen-Klinik in addition to their daily attendance at the International Refugee Organization Altersheim Hospital, Munich.

The language difficulty in the exercises was overcome by the use of expert interpreters during the lecture hours. The best of these were persons who were attending the course. As a rule presentations of cases were given in German, and many of the lectures had previously been translated into German and given to the students. The organization of the mission was completed such a short time before the work commenced that one of the members had barely one week in which to prepare his material and no one had a sufficient opportunity to give to the work the time it deserved.

Before considering the results achieved by the courses it is appropriate to discuss the type of physician who had been enrolled for the work. As Dr. Findlay has pointed out, these persons had been carefully selected, and it was realized by the members of the mission before the work began that the persons to whom they were to give instruction were capable and highly trained. In the address of welcome at the beginning of each course the chairman of the mission stressed the fact that the exercises represented conferences between colleagues and that the only reason why the instructors were in a positon to take the lead in the presentations was because they had been so situated that they had maintained touch with the advances in their specialties during and after the war years, while, on the contrary, their less fortunate European colleagues had been unable to maintain such contact. In many instances it became obvious that the prewar experience and training of some persons in certain phases of the subjects discussed considerably exceeded that of the instructors. This would be of necessity the case when such broad fields of work as general medicine, general surgery and the other specialties under consideration had to be presented each by an individual teacher. This situation is illustrated by the fact that two of the "students" were expert cardiologists each of whom had recently completed a book on electrocardiography. One of these men was of great assistance in discussions and demonstrations on this topic. Several were expert in diseases of the respiratory system; several were pediatricians of many years' experience, and there were a number of highly trained surgeons in the course. The very fact of their familiarity with their own specialties made these men all the more eager to learn of the advances that had been made since they had been in touch with world medicine. By the same token they were ideal students who as a rule realized instantly the value and implications of the new methods and technics which were presented to them. In addition to more complicated matters, discussions and demonstrations of such fundamentals as routine complete physical examinations and history taking were taken up on several occasions, and the group demonstrated to all concerned that their ideas and methods were sound. Such exercises were of benefit to all. The very limitations as to supplies and equipment under which D. P. physicians have been forced to work have emphasized to them the value of many of the less complicated methods of dealing with disease, and in general they demonstrated their ability to excel in such matters.

In discussions with many of the physicians about their work in the displaced persons' camps it became evident that some of them had been showing remarkable energy and initiative under discouraging conditions. The striking health records of the D. P. population to which Dr. Findlay has referred is evidence of this. Many individual examples could be cited; for instance, the two young men, one from Hungary and one from Latvia, who collaborated in a chest survey of 6,000 of their people in which they used a single fluoroscope. This was a pioneer effort which focused the attention of the authorities on the need for such work and resulted in the importation of adequate apparatus and personnel. The same two physicians are now engaged in an extensive study of the condition of children born in displaced persons' camps. A number of experienced surgeons were present in the group, several of whom have been having a large operative experience in hospitals staffed by displaced persons. As has already been mentioned, the number of professors and teachers of lower ranks enrolled in the course was large.

In addition to a familiarity with the professional competence of the physicians taking the courses, the members of this teaching mission have been enabled to become rather intimately acquainted with a good proportion of their students and to form some warm friendships. The results of the work may be considered from three points of view: (1) the professional education of the displaced person physician, (2) the improvement of his morale and (3) the demonstration of his standing as a man and a physician.

As a teaching project the courses appear to have been successful. The students very generally have expressed appreciation and enthusiasm. As to morale, there is no doubt whatever that the opportunity for these physicians to participate in professional discussions and hospital exercises in their normal roles as expert has brought back to them a feeling of dignity and self confidence which, because of the harsh treatment to which they have been subjected, had in many instances sunk to a low level. As to the third point, the evaluation of these persons as members of the profession, it is the unanimous opinion of the members of the Munich Medical Teaching Mission that any country in which one of these physicians eventually settles may count itself fortunate because of the acquisition of a citizen of the highest type who cannot but enrich the life of his community.

Clinical Notes, Suggestions and New Instruments

ACUTE PERITONITIS FOLLOWING RUPTURE OF MESENTERIC LYMPH NODES

Report of Its Occurrence in a Case of Typhoid and in a Case of Paratyphoid

J. WARREN KYLE, M.D.
and
RUSSELL H. PATTERSON, M.D.
Memphis, Tenn.

Although involvement of mesenteric lymph nodes in typhoid and paratyphoid is well recognized, suppuration of these nodes with rupture and peritonitis is rare.[1] We are reporting a case of acute peritonitis due to such rupture, occurring in the fourth week of typhoid, which simulated an acute perforation of a typhoid ulcer. We are also reporting from the records of the John Gaston Hospital a case of paratyphoid in which there was generalized peritonitis due to rupture of a mesenteric lymph node.

REPORT OF CASES

CASE 1.—J. L., a 14 year old white boy, was admitted to the John Gaston Hospital on June 9, 1947, because of fever, periumbilical pain, anorexia and watery diarrhea of one day's duration. This had been preceded by malaise for several days, headache and a chill. The patient had been well until the onset of the present illness. The past history was noncontributory.

On examination, the temperature was 103 F., the pulse rate 118, the respirations 20 and the blood pressure 110 systolic and 68 diastolic. The patient was poorly developed, poorly nourished, febrile and apathetic in appearance. There was moderate tenderness in the epigastrium and the periumbilical region, but no rigidity or abdominal distention. The spleen was not felt. The results of the remainder of the physical examination were negative.

On admission, the white blood cell count was 10,350 and the hemoglobin was 13 Gm. The urinalysis showed a specific gravity of 1.028, albumin (2 plus) and no sugar; microscopic observations were normal. Blood, urine and stool cultures of June 10 were all positive for Eberthella typhosa. The results of typhoid agglutination were positive in dilution of 1 to 320 on June 25 and 1 to 2,560 on July 2.

There was a remittent fever, with temperature of 100 to 104 F., for three weeks. In the fourth week, the temperature declined to an intermittent 100 to 101 F. The patient was feeling fairly well by this time. On the morning of July 3, the twenty-seventh day of his illness, the patient was suddenly seized with a severe continuous generalized abdominal pain. There was nausea but no vomiting. This was followed by a rise in temperature from 99 to 103 F. and increase in pulse rate from 90 to 150. Examination at this time revealed abdominal distention, decided generalized abdominal tenderness, rebound tenderness and rigidity. The tenderness and rigidity were pronounced in the right lower quadrant of the abdomen. Peristalsis was audible.

In approximately two to three hours after its onset, the pain had become more localized in the right lower quadrant. At this time, the white blood cell count was 20,750. A roentgenogram of the chest, taken with the patient in an upright position, showed no free air under the diaphragm.

The patient was operated on approximately five hours after the onset of the pain, with a preoperative diagnosis of ruptured typhoid ulcer. With the patient under cyclopropane anesthesia, a right rectus incision was made and exploration carried out. Distention was seen uniformly throughout the intestinal tract, with a moderate amount of yellowish purulent fluid collected about the distended loops. The peritoneum showed decided hyperemia. What was thought to be typhoid ulcers were palpated through the wall of the lower part of the ileum. No per-

[1] Bell, E. T.: A Text-Book of Pathology, ed. 6, Philadelphia, Lea & Febiger, 1947.

foration was observed. Further examination revealed a group of lymph nodes in the ileocecal region which were enlarged and apparently fused together. Considerable purulent material was being discharged from a point of rupture in this group of nodes. Cultures were taken. The peritoneal cavity was suctioned out and drainage established with a soft rubber tissue drain through a stab wound in the right lower quadrant of the abdomen. The incision was closed without drainage.

The immediate postoperative course was stormy, being characterized by high temperature, accelerated pulse and pronounced apprehension. Treatment consisted of suction siphonage, intravenous administration of fluids, blood transfusions, intramuscular injection of streptomycin, 2 Gm. per day for eight days, intramuscular injection of penicillin, 400,000 units per day for five days and 240,000 units per day for four days, and intravenous and oral administration of sulfadiazine, 4.5 to 6 Gm. per day for fourteen days. Improvement was noted on the third postoperative day, and by the fifth postoperative day the temperature and pulse rate had returned to normal. At this time, suction siphonage was discontinued and all drains removed. The operative wound showed no evidence of infection. Improvement thereafter was rapid, with increasing strength and appetite. Cultures of the stool became negative for typhoid bacilli on July 31 and remained negative thereafter. The culture taken at operation was negative. The patient was discharged as cured on July 31, the twenty-seventh postoperative day.

Case 2.—L. O., a 16 year old Negro girl, was admitted to the Memphis General Hospital (now John Gaston Hospital) on Dec. 29, 1923, complaining of generalized abdominal pain and fever. The onset was insidious two or three weeks before admission, with malaise, weakness and fever. The abdominal pain was not severe. There had been no diarrhea. The past history was noncontributory.

On examination, the pulse rate was 120 and the temperature 104 F. The patient was fairly well nourished, feverish and acutely ill. There was generalized abdominal distention, with a tympanitic percussion note and slight generalized abdominal tenderness. The liver, spleen and kidneys were not felt. The pelvic examination revealed moderate tenderness and fixation about the uterus. There was a sensation of a fluctuant bulging in the left side of the fornix.

Laboratory studies on admission showed a red blood cell count of 3,750,000, hemoglobin, 75 per cent, a white blood cell count of 12,800, with 78 per cent neutrophils and 22 per cent lymphocytes, and normal urine. A urine culture was positive for paratyphoid bacilli. On Jan. 4, 1924, a blood culture was positive for paratyphoid bacilli. The Widal reaction was negative, and the stool culture was negative for typhoid bacilli.

Nausea and vomiting occurred, and the patient had diarrhea. The abdominal observations apparently remained as on admission. There was a remittent fever, with temperature ranging from 102 to 105 F. The pulse rate was rapid, ranging from 110 to 140. Treatment was supportive. On the eleventh hospital day, the patient became much worse; she died the next day, approximately four weeks after the onset of her illness.

Report of Autopsy.—The gross examination showed the peritoneal cavity to contain a moderate amount of fluid. There was pronounced hyperemia of the small intestine and the colon, especially near the ileocecal junction. The intestines were friable and tore with ease. Loops of the large and small intestine were matted together and also to the parietal peritoneum, but no definite adhesions or exudate could be made out grossly. The lumen of the small and large intestine contained a reddish gray material thought to be blood and bismuth. The mucosa of the ileum and the large intestine was edematous, elevated, hyperemic and raw. No definite ulcerations were present. No perforation was seen. There was no definite involvement of Peyer's patches or the solitary lymph follicles. One single mesenteric node was seen which had become extensively necrotic and exuded a thick creamy yellowish material and which was impossible to section. Strangely, every other mesenteric node appeared only slightly increased in size, if at all, and was otherwise normal in appearance. The spleen did not appear enlarged. The remainder of the gross observations were not contributory except for what appeared to be scattered pneumonia in the bases of the lungs bilaterally. Microscopic examination of the small intestine showed much fibrin on the serosal surface. Intermingled in its meshes were many leukocytes and erythrocytes. The capillaries showed decided congestion. There was slight swelling of Peyer's patches and the solitary lymph follicles, but they were not otherwise involved. The spleen showed the microscopic picture of acute splenic tumor. In the lungs, scattered alveoli contained inflammatory elements, with no involvement of the bronchi. The primary diagnosis was paratyphoid with catarrhal hemorrhagic enteritis, necrotic mesenteric lymphadenitis and generalized peritonitis. The subsidiary disease was lobular pneumonia.

COMMENT

It is difficult to estimate the incidence of peritonitis due to suppuration of mesenteric lymph nodes in typhoid except to say that it is uncommon. In 1,472 cases of typhoid in the case records of the John Gaston Hospital since 1922 our case was the only one recorded. In a recent clinical analysis of 360 cases of typhoid from the Charity Hospital of New Orleans, this complication was not discovered at all either by laparotomy or at postmortem examination.[2]

In the older textbooks,[3] the condition is referred to as being rare. Hare and Beardsley [3c] collected 4 cases, reported by others, of abdominal abscesses in typhoid, presumably due to suppurating mesenteric lymph nodes, but this was not proved in every case. Another 2 cases are mentioned by the same authors in which there was well demonstrated suppuration of mesenteric nodes, but no peritonitis was mentioned. In 1 of the latter cases, there was rupture of a mesenteric artery secondary to a suppurating gland near the cecum. In a review of peritonitis without perforation in typhoid, Yates [4] found in the literature 4 other cases of peritonitis due to rupture of mesenteric lymph nodes.

More recently, 1 case of abdominal abscess [5] and 1 case of peritonitis [6] have been reported as due to suppurating mesenteric lymph nodes. A case of pelvic abscess due to the typhoid bacillus was reported in which this was the suspected cause, but it was not proved.[7]

It may be noted that our preoperative diagnosis was acute peritonitis due to a ruptured typhoid ulcer. It would seem difficult, in the absence of free air under the diaphragm, to make a correct differentiation clinically between these two conditions.

This case is the only one of its kind reported in which streptomycin was used. The gratifying postoperative course may have been partly due to this factor.

The case of paratyphoid with generalized peritonitis associated with a ruptured suppurating mesenteric lymph node was the only case with this complication among 78 cases of paratyphoid from the case records of the John Gaston Hospital since 1922. In some of these instances the paratyphoid infection was concurrent with typhoid. This complication would appear to be at least as uncommon in paratyphoid as in typhoid. The complications of paratyphoid are of the same general character and relative incidence as of typhoid, but are much less frequent.[8]

SUMMARY

A case of acute peritonitis in the course of typhoid, due to suppuration and rupture of mesenteric lymph nodes, is reported. A cure was effected following laparotomy and drainage. Streptomycin therapy was used postoperatively. A case of generalized peritonitis in paratyphoid, with the same cause, diagnosed at postmortem examination, is also reported.

Council on Physical Medicine

The Council's Consultants on Roentgen Rays and Radium and Medical Aspects of Atomic Energy adopted the following article as one of at least two treatises on atomic energy for publication under the auspices of the Council. The Consultants on Roentgen Rays and Radium and the Medical Aspects of Atomic Energy are: Drs. W. Edward Chamberlain, Arthur C. Christie, Kenneth S. Cole, L. F. Curtiss, Edwin C. Ernst, Gioacchino Failla, Hymer L. Friedell, R. R. Newell, Eugene P. Pendergrass, Ursus V. Portmann, Lauriston S. Taylor, Shields Warren, Stafford Warren and J. L. Weatherwax. The Council appreciates the cooperation of the Consultants on Roentgen Rays and Radium and the Medical Aspects of Atomic Energy.

Howard A. Carter, *Secretary.*

RADIATION HYGIENE

Hazards to Physicians, Patients, Nurses and Others from Use of Radioactive Isotopes

W. EDWARD CHAMBERLAIN, M.D.
R. R. NEWELL, M.D., *Chairman*
LAURISTON TAYLOR, Ph.D.
HAROLD WYCKOFF, Ph.D., *Alternate*
Subcommittee

The atomic age confronts the medical profession with seemingly unlimited opportunities, but equally with the gravest responsibilities. To match the eagerness with which he plunges into investigation of the tremendous possibilities of advance in medical knowledge, the physician investigator must possess the keenest awareness of the hazards to himself, his patients and working associates involved in the study and manipulation of radioactive isotopes and other products of atomic fission. Fundamental is the fact that there is no antidote to radiation injury. Prevention and unrelenting watchfulness are the requirements for what may be called radiation hygiene. Even physicians who are not engaged in this research must have knowledge of the technics involved, for they may have patients who have been exposed to radiations.

The successful technics developed in the Manhattan District and continuously improved and elaborated by the agencies of the Atomic Energy Commission are, of course, available and must be learned. Many of the radiation hazards met in making the atom bomb were quantitatively, and some of them qualitatively, quite different from what the physician will meet as an investigator. The problems of these controls were solved by the work of many men—physicians, chemists, biologists—in cooperation. A new specialist appeared, called "health physicist," who had to devise and apply methods of detection of hazard and of protection against it. With the continual development of new production processes and research technics, the experience and resourcefulness of the health physicists are continually called on. Hygiene remains, however, the obligation of the medical profession, and physicians must not shrug off this department of it merely because they find the health physicists' art difficult to follow and their science difficult to understand.

In using radioisotopes for medical purposes, the physician will usually have access to such consultation. It seems predictable that teamwork will always be necessary. The Atomic Energy Commission delivers isotopes only for use under control of an isotope committee, assuring sufficient breadth of scientific understanding. But even if the physician has a physicist on his team, he cannot leave radiation hazard just to him. He must, himself, take the responsibility for the health of his associates and of his patients.

In the National Laboratories, where radioisotopes are being used, avoidance of radiation has become a way of life. Radioactive materials are transported by special truck in special 200 pound lead pots and put in and taken out under the chaperonage of some one from the health physics department, who constantly measures the gamma ray intensities and keeps a critical eye on the "technic." Similar chaperonage is provided whenever a scientist does a distillation or other manipulation of an important amount of radioactive substance. At regular intervals, twice a week or twice a day, the health physicist goes through the various rooms and passages hunting with a Geiger counter for radioactive contamination on floors and benches, and sampling the atmosphere for radioactive dust. Working in small teams and lacking a "health physicist," doctors are going to have to do these things for themselves. If they are casual about it, as many have been in the handling of radium, the result will be disaster for all concerned.

Radiation hazard can be put into several classes:

A. External irradiation, beta rays and gamma rays (also roentgen rays)
   1. Injury to patient
   2. Injury to physician and others
   3. Injury to casual personnel
   4. Contamination of laboratories interfering with measurements
   5. Fogging of photographic materials
      (4 and 5 do not, of course, concern hygiene)

B. Internal irradiation, alpha, beta and gamma
   1. Overdosage, general
   2. Bad distribution leading to local overdose
   3. Pick-up of isotopes by physician and others
      (*a*) Inhalation, (*b*) ingestion, (*c*) absorption through unbroken skin and (*d*) through cuts or abrasions
   4. Escape of radioactive materials from control with later pick-up by men, animals or plants

External irradiation from isotopes will seldom endanger the patient, who is usually only briefly exposed; the danger is to the doctor and his associates, who are working with these things all the time. The patients' hazards will arise mostly from errors of judgment or blunders in technic: Doctors make errors in dosage of drugs, too, and sometimes need to administer the antidote. Here it must be repeated that there is no antidote to radiation injury.

With isotopes, doctors are using a novel set of units. A millicurie means 37,000,000 disintegrations per second, an amount in milligrams running from about 16 for plutonium to a millionth for radiosodium. The biologic significance of a millicurie varies with the type and energy of the disintegration and the distribution of the isotope in or on the body. It is at least possible that some doctors will make the superficial but erroneous assumption that they know what a millicurie is because they have used millicurie radon implants.

The great hope for the future of isotopes in therapy is the ability of some of them to concentrate in an organ or tissue. This is at the same time a great hazard, for precise dosage depends on precise estimate of how large a volume of tissue will be holding the dose given, when it has become thus concentrated. The effect depends not on the total dose, but on its specific concentration in the susceptible organ. In fact, for alpha emitters and soft beta emitters, account must be taken of uneven distribution within the organ or within the cell, and one must think of dose in disintegrations per cubic micron.

The millicurie is a disintegration rate, and so the biologic dose depends on how long the irradiation lasts. The millicurie dose falls away according to the half-life of the isotope and also by excretory losses from the body. In all these things there is much room for errors in calculation and in judgment, even gross blunders.

Radium, plutonium and radiostrontium are carcinogenic, having long physical half-lives and lie locked up in the bones with very slow excretion. Two microcuries of radium (being radium, this is 2 micrograms), can kill in seven years, a quantity which for many other elements would rightly be considered a harmless tracer dose.

Hazard from Radioactive Isotopes

	Alpha	Beta	Gamma
Proximity Total Body		Doctor, chemist E. g., P, I, Na, Au	Everybody E. g., Ra, I, Co, Na, As, Au
Proximity Hands		Doctor, chemist, etc.	
		E. g., Ra, Na, P, I, As, C, S, Yt, Au	E. g., Ra, Na, I, As, Au
Surface contamination, especially hands	Generally assumed not effective on skin surface	Doctor, chemist, etc. Beta irradiation dominates gamma; E. g., Ra, P, Na, I, O, S, Sr, Yt, Au	
Inhalation	Everybody in the laboratories		
	Lethal dose of alpha is small E. g., Ra, Rn, Pu, Po	Beta irradiation dominates gamma; some (e. g., rare earths) which are relatively less dangerous when ingested are yet fairly readily absorbed through the lungs	
Ingestion	Everybody; doctors and assistants most likely		
	E. g., Ra, Rn, Pu, Po, etc., even though poorly absorbed	Contaminated wastes may spread hazard far and wide E. g., P, Na, I, C, S, Sr	
Parenteral absorption, wounds, etc.	Doctor and assistants E. g., Pu	Doctor and assistants But unimportant compared to surface contamination	
Percutaneous absorption	Doctor, chemist, etc. Any radioactive isotope in fatty base or in fat solvent		
Bad clinical judgment	Patients and experimental subjects a. By overdosing, total body dose; e. g., P, Na b. Though failure to consider large total accumulation of injury due to isotope's long half-life; e. g., 4 yr. Fe, 4,000 yr. C, etc., and confusion of 8 day I with 12 hr. I c. By erroneous estimation of the concentration in a particular organ; e. g., I, Sr, P		

Gamma rays from isotopes in use and in storage physicians already know how to avoid, for they have years of experience with radium. (It is true that many doctors have destroyed their fingers by careless handling of radium.) But the fact of familiarity with radium would tend to make physicians careless with the other things, for all have learned to take 50 mg. of radium rather casually. But they have not been giving injections or determining test tube reactions with radium. With radium, one fears lest one lose it. With radioisotopes, one ought to fear lest one spill it. One leaves gamma rays behind when one quits the room. When a beta ray emitter is spilled on the fingers the operator carries with him what he cannot wash off. Moreover, beta rays, being highly absorbable, are biologically extremely effective. So even a small millicurie amount gives a large dose by the time that the contaminated cuticle has worn away.

In the chemical laboratory dirty glassware is washed and used again, and spent chemicals are dumped down the drain. Dead animals are carried to the dump or incinerator. Urine and feces go down the sewer. In the isotope laboratory, however, all these may be radioactive. It is a heavy responsibility to see that nothing "hot" is reused and that no dangerous quantities of radioactivity find their way into the sewer, or to an open incinerator or dump. Algae especially, but also higher plants, are capable of reconcentrating some elements which have been diluted and spread on the fields, so that mere dilution cannot be depended on for safety. Wet and dry radioactive wastes have to be collected and isolated, maybe by deep burial.

Many physicians are avid to put radioisotopes to work for medicine, to proceed as fast as possible to apply them to clinical problems and therapeutic arts. Are we physicians going to be able—as a profession—to proceed at equal speed in learning the art of protecting our patients, ourselves, our associates and the communities we live in from the grave and insidious dangers of these very poisonous substances? This paper is intended to point out the dangers and to make some suggestions for avoiding them.

The accompanying table is offered as a graphic summary of the hazards that have been discussed.

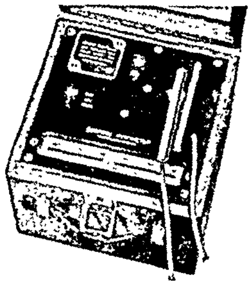
The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

RAUH SURFACE PYROMETER ACCEPTABLE

Manufacturer: E. M. Rauh & Co., Inc., 2 Parker Avenue, Buffalo 14, N. Y.

The Rauh Surface Pyrometer is a device for making rapid surveys of the skin temperature of the human body. The apparatus is enclosed in a mahogany-finished case measuring 20 by 20 by 20 cm. (17¾ inches). The whole weighs 2.3 Kg.; the shipping weight for domestic shipment is about 2.7 Kg., and for foreign shipment about 7.3 Kg. (5, 6 and 16 pounds respectively). The standard model operates on two dry cells needed to supply the light source; models for operation on direct or alternating current are also available.

The sensing element is at the end of an applicator which is connected by a cable to the instrument in the case. This element is a thermopile of small mass, since the smaller the mass to be warmed (or cooled) by the contact with the skin, the quicker and more accurate will be the reading. The current from the thermopile is recorded by a mirror suspended in such a way as to reflect light on a transparent scale; the latter can be read in either Centigrade or Fahrenheit within the range from 15.5 to 43 C. (60 to 110 F.).



Rauh Surface Pyrometer.

The instrument has been examined in the Council laboratory, and evidence of its performance under clinical conditions has been obtained from sources acceptable to the Council. Temperature measurements taken with this instrument must be interpreted, because they are affected by all the variables known to influence skin temperatures. However, the instrument is of value, for instance, in making rapid surveys of the surface temperatures of symmetric areas of two extremities, where circumstances give a basis of comparison. The data are of use in cases of peripheral vascular disease and may help in the differential diagnosis between organic vascular occlusions and fluctuations of vasomotor tone.

The Council on Physical Medicine voted to include the Rauh Surface Pyrometer in its list of accepted devices.

SANBORN INSTOMATIC CARDIETTE ACCEPTABLE

Manufacturer: Sanborn Company, 39 Osborn Street, Cambridge 39, Mass.

The Sanborn Instomatic Cardiette is a portable electrocardiograph weighing 10.4 Kg. (23 pounds). In the recording mechanism a beam of light is cast onto a strip of sensitized paper 5.75 cm. (2¼ inches) wide. The galvanometer deflection is indicated by a shadowed line moving across the paper. This results in a white line 2 mm. wide against a dark background on the developed photographic record. Narrow white lines also mark the strip into 1 mm. squares, every fifth one of which is slightly wider. A 30 meter (100 foot) roll of sensitized paper is contained in a removable magazine equipped with a red window to permit examination of the paper supply. A slot, with hinged cover, allows marking on the back of the record.

The paper is pulled past the recording point and into a removable light tight container which makes it possible to take the exposed record to the dark room. Removing this container from the machine automatically cuts the film. To prevent losing the end of a record, it is necessary to allow an extra few inches to pass into the container before removing from the machine.

The paper drive is by means of a hand wound spring motor which will run for four minutes (610 cm. or 20 feet of record) on one winding. The speed is adjustable if correction becomes necessary. A rewind indicator and film footage indicator are provided on the panel.

The apparatus submitted was subjected to the tests called for by the Minimum Requirements for Acceptable Electrocardiographs published by the Council on Physical Medicine in THE JOURNAL (134:455 [May 31] 1947). It was found to satisfy these requirements.

The Council on Physical Medicine voted to include the Sanborn Instomatic Cardiette in its list of accepted devices.

PURITAN 11-GA OXYGEN INHALATION APPARATUS ACCEPTABLE

Manufacturer: Puritan Compressed Gas Corp., 1240 W. Jackson Blvd., Chicago 7.

This portable assembly consists of a safety pressure-reducing regulator equipped with a flow gage calibrated in liters per minute; a humidifying assembly, which is to be attached to the back of the regulator by a removable clamp; two bottles fitted with two-hole stoppers and four metal tubes, one having a gas spray attachment; and three pieces of pure gum tubing. Also included in this unit is a cylinder base designed to prevent possible tipping when placed on the bottom of either D or E size cylinders. A wrench is enclosed for operating the cylinder valve. If it is desired to use a nasal catheter for administration of oxygen, the catheter may be attached to the pure gum tubing in place of the face cone.

The Council on Physical Medicine voted to include the Puritan 11-GA Oxygen Inhalation Apparatus in its list of accepted devices.

COLLINS METABOLEX ACCEPTABLE

Manufacturer: Warren E. Collins, Inc., 555 Huntington Avenue, Boston 15, Mass.

The Collins Metabolex is an apparatus designed for use in determining basal metabolic rates. It is mounted on a three-legged stand provided with casters; the stand bears, underneath, the oxygen tank needed for filling the spirometer which is on top. The spirometer is of the accordion or bellows type, but has the general form of a circular cylinder and moves vertically. Tracings are made on an aluminum drum driven either by spring movement or by electric motor (optional). If the spring movement is used, no electric connections are necessary. If the electric clock is used, a 110 volt controlled-frequency alternating current is requisite.

With the stand, the apparatus is 126 cm. (49½ inches) high and weighs 16 Kg. (35 pounds). Without the stand, it is 51 cm. (20 inches) high and weighs 11.3 Kg. (25 pounds). The floor space required is 51 by 61 cm. (20 by 24 inches). The reservoir for soda lime has a capacity of 3.8 liters (4 quarts). The oxygen tank provided for is the 300 liter (80 gallon) size. The shipping weight of the apparatus alone is 17 Kg. (37½ pounds); that of the stand is 9.5 Kg. (21 pounds).

The apparatus, on examination, was found to be simple and attractive in design, and to give satisfactory results in the hands of experienced users.

The Council on Physical Medicine voted to include the Collins Metabolex in its list of accepted devices.

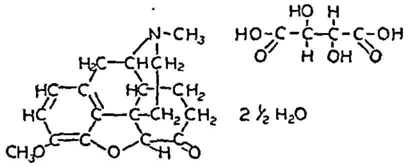
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

DIHYDROCODEINONE BITARTRATE.—Hycodan Bitartrate-Endo.—The hydrated bitartrate of dihydrocodeine. $C_{18}H_{21}O_3N \cdot C_4H_6O_6 \cdot 2\frac{1}{2}H_2O$.—M. W. 494.26.—The structural formula of dihydrocodeinone bitartrate may be represented as follows:



Actions and Uses.—Dihydrocodeinone bitartrate is essentially similar in action to codeine salts but is more active when compared with codeine on a weight basis and is also more addicting. It is useful primarily as an antitussive and may be used for this purpose in the same manner as codeine, over which it has no clearcut advantage.

Dosage.—Adults, 5 to 15 mg., 3 or 4 times within a 24 hour period. The higher dosage is rarely necessary. Children 2 years of age or older may be given one-half the adult dose; younger children one-quarter the adult dose.

Tests and Standards.—

Dihydrocodeinone bitartrate occurs as a white, odorless, crystalline powder. It is freely soluble in water and slightly soluble in alcohol.

Dissolve about 100 mg. of dihydrocodeinone bitartrate in 1 cc. of water, add 3 drops of ammonia T. S. to precipitate the free base and allow the mixture to stand for 1 hour. Collect the precipitate on a small suction filter (retain the filtrate), wash it with 1 cc. of cold water and remove the excess water by suction. Dry the precipitated dihydrocodeinone for 2 hours at 100 C.: it melts at 194-196 C.

To the filtrate obtained after separation of the free base, add sufficient silver nitrate T. S. to produce a cloudy solution; then add just sufficient ammonia T. S. to render the solution clear, and warm the mixture on a steam bath: a deposit of metallic silver on the walls of the test tube indicates the presence of tartrates.

To about 3 mg. of dihydrocodeinone bitartrate dissolved in 0.1 cc. of water, add 5 cc. of sulfuric acid containing 5 mg. of selenious acid per cc.: the mixture yields a green color which changes to blue and then slowly to purple *(distinction from morphine, which yields a blue color changing to green and then to brown).*

Dissolve about 20 mg. of dihydrocodeinone bitartrate in 5 cc. of sulfuric acid, add 1 drop of ferric chloride T. S. and warm in a steam bath: the solution does not change in color when heated *(distinction from codeine, which gives a purple color).*

Dissolve about 100 mg. of dihydrocodeinone bitartrate and 200 mg. of hydroxylamine hydrochloride in 1 cc. of water. Cover with a watch glass and heat on a steam bath for one-half hour. Cool in ice water and add strong ammonia solution until the oxime precipitates. Collect the oxime on a filter, wash with 3 cc. of water containing 1 per cent ammonia (made by diluting 1 cc. ammonia T. S. to 10 cc.), remove the excess water by suction and dry the precipitate for 4 hours at 100 C.: the dihydrocodeinone oxime melts with decomposition between 264 and 268 C.

Prepare a one-tenth molar solution of dihydrocodeinone bitartrate in freshly boiled and cooled distilled water: the pH of the solution is between 3 and 4. Ignite about 200 mg. of dihydrocodeinone bitartrate, accurately weighed; the ash residue is not more than 0.05 per cent. Add about 100 mg. of dihydrocodeinone bitartrate to 5 cc. of sodium hydroxide T. S. and heat the mixture to boiling: no odor of ammonia is detected.

Transfer about 150 mg. of dihydrocodeinone bitartrate, accurately weighed, to a 250 cc. separator with the aid of 10 cc. of water. Drop a small piece of red litmus paper into the funnel and then add, dropwise, ammonia T. S. until the litmus paper just turns blue (about 3 drops). Extract six times with 25, 25, 20, 20, 15 and 15 cc. portions of chloroform, and collect the chloroform extracts in a 250 cc. Erlenmeyer flask after filtering through a small plug of cotton. Evaporate the combined chloroform extract almost to dryness, remove the flask from the steam bath, blowing off the remainder of the chloroform with a stream of air. Add 5 cc. of neutral alcohol and heat on a steam bath until the residue dissolves. Add 2 drops of methyl red indicator T. S. and then 20 cc. of 0.02 *N* sulfuric acid. Heat on a steam bath until the alcohol starts to reflux. Cool the flask to room temperature and titrate the excess acid with 0.02 *N* sodium hydroxide. Each cc. of 0.02 *N* sulfuric acid consumed is equivalent to 0.009884 Gm. of dihydrocodeinone bitartrate: the amount of dihydrocodeinone bitartrate found is not less than 98 per cent of the sample as received.

Endo Products, Inc., Richmond Hill, N. Y.

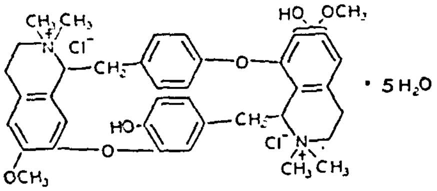
Hycodan Bitartrate *(Powder)*: 1 Gm., 5 Gm. and 10 Gm. bottles.

Syrup Hycodan Bitartrate: 5 mg. per 5 cc., 475 cc. and 3.74 liter bottles.

Tablets Hycodan Bitartrate: 5 mg.

U. S. trademark 399,421.

***d*-TUBOCURARINE CHLORIDE.** — The crystalline chloride of a quaternary base alkaloid obtainable from the bark and stems of *Chondodendron tomentosum* and related species.—$C_{38}H_{44}Cl_2N_2O_6 \cdot 5H_2O$.—M. W. 785.74. *d*-Tubocurarine chloride is standardized biologically by the rabbit "head-drop" method. The standard "head-drop" dose, HD_{50}, calculated as *d*-tubocurarine chloride pentahydrate, is 0.15 mg. per kilogram of body weight. The structural formula of *d*-tubocurarine chloride may be represented as follows:



Actions and Uses.—*d*-tubocurarine chloride may be used in conditions in which it is desirable to reduce the tone or contractile power of skeletal muscle. It is useful with light general anesthesia to obtain greater relaxation of the musculature in abdominal surgery and orthopedic manipulative procedures, to diminish the violence of muscular contractions during metrazol or electric shock therapy, and temporarily to lessen spasticity due to injury of the central nervous system or in certain spastic states of neurologic origin. It may also be used as a diagnostic agent in cases suspected to be affected with myasthenia gravis.

Dosage.—In conjunction with light surgical or orthopedic anesthesia, premedication should be carried out as usual. The following doses are applicable with general anesthetics *except ether, when only one-third of the recommended dose should be employed.* The patient is maintained at light surgical anesthesia until the stage of the operation is reached at which the greatest muscular relaxation is required. At that time 6 to 15 mg. may be given as a single intravenous injection. This is sometimes effective in about 2 minutes; if respiration ceases, the anesthetist must be prepared to continue the pulmonary exchange by pressure on the bag of the anesthetic apparatus. The dose may be calculated on the basis of 1 mg. for each 10 lb. of body weight (*one-third this amount when ether is the anesthetic*).

In therapeutic shock treatment, the usual dose is 3 mg. for each 40 lbs. of body weight; for greater safety 3 mg. less than the calculated amount should be used as the initial dose and the intravenous injection should always be given over a period of not less than 90 seconds. In spastic states, where the drug is used to permit training in the voluntary use of muscles, it may be administered intramuscularly at four day intervals. The dose is determined by trial, beginning with 3 mg. for each 40 lbs. of body weight and gradually increasing the dose until the amount producing best results is found. As a diagnostic test for myasthenia gravis, 0.3 mg. per 40 lbs. of body weight is given intravenously; marked exaggeration of symptoms appears within two minutes. As soon as a positive reaction is confirmed, the curare effect should be antagonized immediately by the intravenous injection of 1 cc. of neostigmine methylsulfate, 1:2,000 combined with 0.6 mg. of atropine sulfate. The former drug should always be on hand to combat respiratory failure during the use of curare.

Solutions of *d*-tubocurarine chloride used in conjunction with pentothal sodium intravenous anesthesia may be admixed with a solution of pentothal sodium for simultaneous administration of both agents. Solutions of *d*-tubocurarine chloride are available in concentrations of 3 mg. (20 units) per cubic centimeter and 15 mg. (100 units) per cubic centimeter. The acidity of these solutions causes only momentary precipitation of curare-barbiturate mixtures when added in amounts to avoid undue dilution of the pentothal sodium solution: limit for solution *d*-tubocurarine of 3 mg. (20 units) per cc., is 7.5 units per 25 mg. pentothal sodium in 1 cc.; for solution *d*-tubocurarine of 15 mg. (100 units) per cc., 10 units per 25 mg. pentothal sodium in 1 cc. Optimal results for most operative procedures have been obtained by using 5 units of the higher potency *d*-tubocurarine solution per each 1 cc. of a 2.5 per cent solution of pentothal sodium. This mixture is made up by adding 1 cc. of high potency (100 units per cc.) solution of *d*-tubocurarine chloride to 19 cc. of 2.5 per cent solution of pentothal sodium and when so made from the high potency *d*-tubocurarine chloride solution will keep for about 10 days. It is administered in the same manner as pentothal sodium alone, with slow induction, 1 or 2 cc. at a time. The average total dose of the mixture varies from 15 to 20 cc. Other ratios and technics may be worked out to advantage in individual cases. *The high potency solution of d-tubocurarine chloride, 15 mg. (100 units) per cc., should never be injected without dilution because of the danger of overdosage by too rapid administration.* *d*-Tubocurarine chloride-barbiturate combination anesthesia is contraindicated in patients with respiratory deficiencies, pulmonary disorders, renal dysfunction, liver disease and myasthenia gravis.

Tests and Standards.—

d-Tubocurarine chloride occurs as a colorless or yellowish-white to gray or light brown, odorless, crystalline powder. It is soluble in water, slightly soluble in alcohol, and practically insoluble in chloroform and ether. When previously dried at 100° C. for 4 hours, it melts with decomposition somewhere between 265° and 278° C. provided the melting point tube is placed in a bath preheated to 260° C.

Prepare a stock solution of 0.1 Gm. of *d*-tubocurarine chloride in 10 cc. of water: it is colorless or yellowish and free of insoluble material. Dilute 1 cc. of the stock solution to 100 cc. with water and to 2 cc. of this solution add 3 cc. of Folin-Ciocalteu phenol reagent (*Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists,* ed. 6, p. 319), previously diluted (1:3) with water, and adjust the volume to 25 cc. with water. Add 2 cc. of 20 per cent sodium carbonate solution, mix, and heat the mixture for 3 minutes in a boiling water bath: a brilliant blue color develops.

Dilute 0.5 cc. of the stock solution with 10 cc. of water, add 0.2 cc. of sulfuric acid and 2 cc. of a 1 per cent potassium iodate solution, mix thoroughly and warm in a water bath for 30 minutes: a yellow color develops.

To 1 cc. of the stock solution add 1 cc. of a 4 per cent Reinecke's salt solution: a pink precipitate results. To 1 cc. of the solution add 1 cc. of saturated picric acid solution: a yellow precipitate results. To 1 cc. of the stock solution add 1 cc. of silver nitrate T.S.: a white precipitate forms, soluble in ammonia T.S.

Dry about 0.1 Gm. of *d*-tubocurarine chloride, accurately weighed, in a tared weighing bottle at 100° C. for 4 hours: the loss in weight does not exceed 11.5 per cent.

Transfer 0.2 Gm. of *d*-tubocurarine chloride, accurately weighed, to a separatory funnel containing 200 cc. of water. Add 5 cc. of saturated sodium bicarbonate solution and extract with three 20 cc. portions of chloroform. Wash the combined chloroform extracts with 10 cc. of water, filter through a pledget of cotton into a tared beaker, evaporate and dry at 100° C. for 1 hour: the weight of the residue does not exceed 3 per cent calculated on the dry basis. The residue is insoluble in water, but soluble in diluted hydrochloric acid.

Transfer about 0.15 Gm. of *d*-tubocurarine chloride, accurately weighed, to a 100 cc. Erlenmeyer flask and add 10 cc. of water, 5 cc. of diluted nitric acid and exactly 25 cc. of fiftieth-normal silver nitrate. Add 5 cc. of nitrobenzene and swirl the contents of the flask to entrap the precipitate. Add 2 cc. of ferric ammonium sulfate T.S. and titrate the excess silver nitrate with fiftieth-normal ammonium thiocyanate. Each cc. of fiftieth-normal silver nitrate is equivalent to 0.000709 Gm. of chlorine: the chlorine content found is not less than 9.5 nor more than 10.2 per cent, calculated to the dried substance.

Transfer about 0.1 Gm. of *d*-tubocurarine chloride, accurately weighed, to a 10 cc. calibrated flask, dissolve the salt and make up to volume with water. Let the solution stand for 3 hours and determine the optical rotation in a 100 mm. polarimeter tube: the specific rotation, $[\alpha]^{25}_{D}$, calculated from the observed rotation and the concentration (expressed in grams of dried *d*-tubocurarine chloride per 100 cc. of solution) is not less than + 208 degrees nor more than + 217 degrees. (The most probable value of the specific rotation for pure anhydrous *d*-tubocurarine chloride is + 215°.)

The potency of *d*-tubocurarine chloride is determined by observation of the "head-drop" response following intravenous injection of the drug in rabbits. (For assay methods see H. A. Holaday, U. S. Patent 2,397,417; R. F. Varney, C. R. Linegar and H. A. Holaday, *Federation Proc.*, **7**, Part 1: 261 (March) 1948; and G. M. Everett, *J. Pharmacol. & Exper. Therap.* **92**: 236 (March) 1948.)

Abbott Laboratories, North Chicago, Ill.

Solution *d*-Tubocurarine Chloride: 3 mg. per cc., 10 cc. vials. Preserved with benzyl alcohol 0.9 per cent.

E. R. Squibb & Sons, New York

Solution *d*-Tubocurarine Chloride: 3 mg. (20 units) per cc., 10 cc. vials.

Solution *d*-Tubocurarine Chloride (High Potency): 15 mg. (100 units) per cc., 1 cc. ampuls.

THE D. P. DOCTOR

Recently the press, at least in the Midwest, has been agitated by the fact that a Wisconsin community arranged for the arrival and entrance into practice of a physician from abroad who had lost contact with his motherland, and then discovered that he could not qualify for licensure. Several newspapers wanted to make an issue of the situation. Reporters exhibited great distress when they discovered that a doctor cannot practice medicine in the United States without a license from the state in which he wishes to practice. The laws regulating medical licensure were not adopted for the protection of the medical profession but for the protection of the American people against unqualified and incompetent doctors. The laws of the various states differ. Some states require full citizenship; others require first papers; some require a year of internship in a hospital within the state; many of them demand fully accredited credentials which physicians from foreign countries frequently do not have.

The medical schools of many of the foreign countries have been in a deplorable state since the beginning of the Nazi invasions. The medical schools of Germany are today in a deplorable state, as are those of many other European countries. Recently Dr. Irving S. Wright[1] reported on a study of the schools of Europe. One of the chief difficulties has been the attempt of the schools to take on more students than they could teach properly, since they suffer from a lack of teaching personnel and equipment. The Editor of THE JOURNAL visited the displaced persons camp at Altersheim in a recent trip to Europe and while there conferred with a mission which was endeavoring to bring the D. P. physicians up to date in medical matters. One must realize that Europe was completely shut off from scientific information developing elsewhere in the world during at least the years 1939 to 1944. Foreign doctors knew nothing whatever of the development of antibiotic drugs, of new methods of anesthesia and of many other new medical technics which had been developed elsewhere. Estimates indicate that there are about 2,000 physicians in D. P. camps. It is unlikely that more than a few of these will eventually come to the United States. Many of them will accompany the people with whom they fled from their own countries. Most of them had such a difficult time keeping alive during their flight that they had little opportunity to keep abreast of medical knowledge. The younger physicians graduated from medical schools which have had a serious time trying to survive since 1933.

The International Refugee Organization established in 1948 a special board to register the medical credentials of displaced and refugee physicians and other medical personnel. The International Refugee Organization is issuing to each person registered a certificate stating the particulars of his medical qualifications. They report that there are now in the United States zone of Germany 1,461 registered refugee physicians, of whom 901 are general practitioners. These physicians come from all of the countries of Europe, and they represent a great variety of religious groups. The majority are Catholic, and about 300 are Jewish. It should be remembered that the majority of the Jewish physicians went to the German concentration camps and were destroyed either by gas or by some other technic commonly referred to in connection with Russian activities as being "liquidated."

The difficulties which confront a foreign physician in securing opportunity to practice in the United States are far less rigorous than those confronting physicians from the United States who might wish to practice abroad. There are few physicians from the United States practicing in Great Britain, and the difficulties in France are even greater. The Latin American countries practically forbid practice by a physician from the United States, making the conditions so severe that few physicians from the United States would wish to attempt to qualify. The methods of medical education that prevail in most other countries are quite different from those in the United States.

The state medical licensing boards have considered the cases of D. P. physicians with the utmost sympathy and liberality. Many of them have been given opportunity to take examinations three, four or more times, and in one instance a physician took the examination ten times before he finally passed. He had spent the intervening time in study and was thereby a better physician.

Ultimately, under the auspices of the World Medical Association or of the United Nations, some conference may be held to consider the varying qualifications demanded of a physician in different countries with a view toward greater standardization of medical education and licensure.

CANCER OF THE LUNG IN CHROMATE WORKERS

The alarming rise in the incidence of cancer of the lung during the last three decades in many countries advanced death from this tumor into second place on the cancer-mortality list for males. The majority of investigators found that occupational factors did not play any demonstrable part in pulmonary cancers and could not account for the increase. However, such conclusions were drawn as a rule from the data in patients' histories, and were, therefore, of little scientific value. Specific occupational exposures responsible for industrial cancers are usually sustained some three to thirty years previous to the manifestation of the cancer and for this reason usually appear to be without relation to the occupational information of the general type recorded in patients' histories and death certificates. The recent report by Machle and Gregorius [1] on cancer of the lung among workers in seven American chromate plants provides definite evidence of the occupational origin of these tumors. The epidemiologic study of deaths from pulmonary cancer among workers in the major factories of chromates showed that in a total of 193 deaths from all causes there were 66 deaths from cancer of all sites and 42 deaths from pulmonary cancer (21.8 per cent of all deaths). In addition to an excessive total cancer death rate in this occupational group, the pulmonary cancer ratio was 16 times the expected ratio of 1.3 per cent. The individual ratios of pulmonary cancer in the various plants ranged from 13 to 31 times the normal, while the crude death rate for this type of tumor was 25 times the normal, the range of excess for the different plants being from eighteen to fifty fold. This evidence confirms previous reports from German chromate factories [2] and implicates chromates as carcinogenic agents. Although Machle and Gregorious stated that, according to their observations, chromic acid and basic chromium sulfate are apparently noncarcinogenic, a fact of considerable importance from the point of view of hazard to users of bichromates and chromic acid, this claim lacks adequate proof from thorough investigation of industries and workshops handling these chemicals. In present circumstances these chemicals must be considered as potentially carcinogenic.

Other occupational activities also carry an increased liability to cancer of the lungs and nasal sinuses. The inhalation of hot tar fumes by stokers in generator plants, of radioactive dust and gases by miners handling radioactive ores and of asbestos dust in various asbestos industries has resulted in an excessive incidence of pulmonary cancer among members of these occupations, while workers of nickel-copper refineries have a special liability to cancer of the nasal sinuses and of the lungs. Doubtless, other industrially important agents possess similar properties, although this fact has not yet been recognized or recorded. Fluctuations of the incidence of pulmonary cancer between different regions and during various periods probably are in part attributable to differences in the quantitative and qualitative aspects of the environmental carcinogenic spectrum. A fuller knowledge of the epidemiology and etiology of cancer of the respiratory organs depends on a more extensive and thorough analysis of the occupational activities and other environmental factors of patients with cancer of the lung.

TUBERCULIN ALLERGY

In 1942 Landsteiner [1] challenged conventional theories of anaphylaxis by demonstration that acquired skin sensitivity to simple chemical compounds is not dependent on circulating antibodies. Such sensitivity was apparently due to specific acquired biologic deficiencies or abnormalities of tissue cells. Guinea pigs were rendered specifically hypersensitive to picryl chloride by injection of picryl chloride–stroma conjugates. When a drop of an oil solution of picryl chloride was subsequently put on the skin, intense erythematous reactions were noted. A passive transfer of this skin sensitivity was impossible by serum transfer but was found possible by intraperitoneal or intravenous injection of peritoneal exudate. The transfer was not due to the clarified fluid in this exudate, but to its cellular elements. Similar cytologic transfer of acquired skin sensitivity was subsequently demonstrated with other simple chemical compounds.

Clinical interest in the Landsteiner cytogenic allergy was increased by the subsequent demonstration that the same type of cellular transfer is possible in hypersensitivity to tuberculin. Chase,[2] of the Rockefeller Institute, rendered albino guinea pigs hypersensitive to tuberculin by subcutaneous injections with heat-killed human tubercle bacilli suspended in liquid petrolatum. Between five and nine weeks later the cutaneous reactivity to tuberculin was pronounced. Exudates were induced in these animals by an intraperitoneal injection of 28 cc. of liquid petrolatum. Forty-eight hours later the peritoneal cavities were washed out with heparized Tyrode solution containing gelatin or normal guinea pig serum.

The washings were combined and cells recovered from the aqueous layer by minimal centrifugation. The sedimented cells were repeatedly washed with Tyrode's solution plus a tenth volume of normal guinea pig serum. The yield of cells amounted to 0.1 to 0.15 cc. per donor. The sediment was composed of 15 to 30 per cent polymorphonuclear leukocytes, 20 to 35 per cent lymphocytes and 50 to 65 per cent large mononuclear cells.

The combined cells from 2 to 10 donors were immediately injected intraperitoneally or intravenously into normal albino guinea pigs. The animals were then given periodic skin tests with old tuberculin. After a latent period of two to three days following intraperitoneal injection, or twenty to thirty-six hours after intravenous injection, tuberculin skin reactions were noted. The sensitivity increased to a maximum by the end of seventy-two to ninety-six hours, at which time the routine skin test led to a diffuse indurated reaction about 16 mm. in diameter with a white center 9 mm. in diameter and a 4 mm. brownish necrotic central zone. After the fifth day, control animals exhibited active sensitization to the tuberculin preparation used in the periodic tests, largely a sensitivity to the broth medium. The tests were discontinued at this time.

[2] Chase, M. W.: Proc. Soc. Exper. Biol. & Med. 59: 134, 1945.

In addition to the exudate cells from the peritoneal cavity, cells from the spleen or lymph nodes were found capable of transferring tuberculin hypersensitivity. The cells become largely or entirely inactive on being heated to 48 C. for fifteen minutes, or after twenty-four hours' storage in the ice box.

This reported cytologic transfer of tuberculin hypersensitivity has been adequately confirmed by Cummings[3] and his associates, and studied in greater detail by Stravitsky[4] of the California Institue of Technology. Stravitsky found that a similar transfer of acquired tuberculin hypersensitivity was possible by a massive transfer of whole blood from tuberculous guinea pigs. He expressed the opinion that circulating lymphocytes in this whole blood were responsible for this transfer. Attempts to transfer sensitivity by means of various crude extracts of tuberculous lymphocytes, peritoneal exudates, lymph nodes or spleen, however, gave negative results.

It has been shown by Moen,[5] Favour[6] and others that lymphocytes from tuberculous mice and guinea pigs are rapidly lysed (or autolysed) on contact with a small amount of tuberculin. That the same type of lysis (or autolysis) is demonstrable with human leukocytes was subsequently shown by Fremont-Smith[7] of Harvard Medical School. White cells were obtained by fractional centrifugation of heparized human blood. Experiments were performed on the leukocytes from three groups of subjects: (*a*) tuberculin-positive patients with bacteriologically proved active, severe tuberculosis, (*b*) subjects with positive skin reactions but no demonstrable clinical tuberculosis and (*c*) healthy persons with negative tuberculin skin reactions.

Cytolysis was demonstrated by adding 0.2 cc. of the white cell suspension (7,000 to 15,000 per cubic centimeter) in fresh human serum to 0.2 cc. of fresh normal human serum containing 25 micrograms of tuberculoprotein per cubic centimeter. The resulting mixture was immediately immersed in a water bath at 37 C. Total and differential cell counts were made at stated intervals. These counts showed that with leukocytes from patients with active severe tuberculosis there was as much as a 60 per cent specific destruction of the lymphocytes and a 90 per cent destruction of neutrophil leukocytes by the end of ninety minutes.

Control tests with white cells from healthy tuberculin-positive or tuberculin-negative subjects elicited negative reactions. Parellel tests with leukocytes suspended in heated normal human serum were also negative in result. This was interpreted by the Harvard investigator as evidence that serum complement plays a role in tuberculin cytolysis. The mechanism of this lysis and of the cytogenic transfer of tuberculin hypersensitivity was otherwise not determined.

Current Comment

THE OREGON AND SAN DIEGO SUITS

Elsewhere in this issue appear the complaints against the medical societies of Oregon and of San Diego, California, which explains the reasons alleged for undertaking these actions. Apparently the basic question is again the right of a medical society to refuse membership to a physician whom it does not find acceptable, the right of a medical society to oppose any group of physicians organized to practice as an agency rather than as individuals, and the right of a hospital to bar from its staff persons whom it finds unacceptable either because they are not members of a medical society or for some other reason. THE JOURNAL has been publishing recently a series of articles which deal with the formation of groups and the practice of medicine by groups of physicians. The idea of group practice is not new. More recently, however, the development of groups has been associated with solicitation of patients by a variety of technics and also with the establishment of insurance ventures of one kind or another to cover payment for medical services. As yet a standard form has not been developed for practice of this kind. It is not surprising that there should be differences of opinion among physicians in any given area as to whether such forms of medical practice represent technics that are for the good of the patient or for his exploitation. Unfortunately these actions seem to be related to political ventures in the field of health, such as Mr. Ewing's recent insistence on a nationwide compulsory sickness insurance program and Mr. Truman's advocacy of the same legislation. The medical profession of the United States has shown in no uncertain terms its opposition to government-controlled medical practice and equally its opposition to medical practice as a business. Some of the cooperative ventures in public health thrive by exploitation of the physician and by the delivery of a low quality of medical service. No doubt these cooperative ventures have likewise been interested in breaking the prestige of the medical organizations in various communities so that they might proceed quite unhampered in their activities. In any event, now that the matter has been brought into the courts, a better understanding of the difficulties will ensue.

ORGANIZATION SECTION

COMPLAINTS FILED AGAINST TWO MEDICAL SOCIETIES

Prepared by the

Bureau of Legal Medicine and Legislation, American Medical Association

There follow condensations of the complaints recently filed, respectively, against the Oregon State Medical Society, and others, under the Sherman Anti-Trust Act, and against the San Diego County Medical Society, and others, under the laws of the State of California.

United States of America, Plaintiff v. Oregon State Medical Society, Oregon Physicians' Service, Clackamas County Medical Society, Clatsop County Medical Society, Columbia County Medical Society, Douglas County Medical Society, Jackson County Medical Society, Lane County Medical Society, Marion-Polk Counties Medical Society, The Multnomah Medical Society, W. W. Baum, John Besson, J. P. Brennan, John H. Fitzgibbon, Charles E. Hunt, Gordon B. Leitch, K. H. Martzloff, and E. H. McLean, Defendants.

Filed in the District Court of the United States for the District of Oregon, Oct. 18, 1948.

The complaint charges that beginning on or about Jan. 1, 1936, the defendants have been engaged in a combination and conspiracy to restrain and monopolize interstate trade and commerce in the business of selling and furnishing prepaid medical care in Oregon and in other states, in violation of Sections 1 and 2 of the Sherman Anti-Trust Act.

The conspiracy, the complaint alleges, has consisted of a continuing agreement and concert of action among the defendants: (1) to monopolize prepaid medical care business in Oregon and between that state and other states; (2) to limit the scope of medical care to be provided by prepaid medical care plans in Oregon; (3) to prevent, hinder and obstruct prepaid medical care organizations other than those sponsored by the defendants from continuing to engage in or from engaging in the business of selling and furnishing prepaid medical care in Oregon and in other states; (4) to restrain residents of Oregon and other states from entering into or continuing under prepaid medical care plans not sponsored or supported by the defendants; (5) to prevent physicians from cooperating in prepaid medical care plans not sponsored or approved by the defendants; (6) to restrict the use of hospital facilities by physicians cooperating in prepaid medical care plans other than those sponsored or approved by the defendants, and (7) to prevent Oregon hospitals from allowing their facilities to be used by physicians and patients associated with prepaid medical care plans other than those sponsored or approved by the defendants.

The combination and conspiracy alleged, the complaint continues, have been effectuated by the defendants in the following specific manner: (1) they have hindered and obstructed prepaid medical care organizations in their attempts to procure and retain qualified physicians to cooperate with them; (2) they have expelled, threatened and incited the expulsion from medical societies of physicians cooperating in prepaid medical care plans other than those sponsored or approved by the defendants; (3) they have formed and promoted their own prepaid medical care plans with the intent to drive out, hinder and obstruct other commercial medical care plans operating in Oregon; (4) they have interfered with commercial prepaid medical care organizations other than those sponsored or approved by them in obtaining hospital facilities for their members; (5) they have refused to treat patients and have caused others to refuse to treat patients who are members of a prepaid medical care plan not endorsed by defendants unless the patient pays cash; (6) they have refused and encouraged other physicians to refuse to give patients who are members of a prepaid medical care plan not endorsed by the defendants itemized statements that will enable the patient to be reimbursed under the plan to which he has subscribed; (7) they have refused to consult or assist and have encouraged others not to consult or assist physicians who treat members of a prepaid medical care plan not endorsed by them; (8) they have spread false propaganda for the purpose of discrediting any prepaid medical care plan not endorsed by them; (9) they have agreed among themselves and with others not to compete with each other for prepaid medical care business or with other similar organizations approved by or affiliated with them, and (10) they have succeeded in making hospital facilities in Oregon available only to members of the defendant Oregon Medical Society and its component county medical societies and have restricted and excluded other qualified physicians cooperating in prepaid medical plans other than those sponsored or approved by the defendants from access to such facilities.

The complaint, after attributing certain effects to the activities alleged to have been engaged in by the defendants, concludes with the prayer: (1) that the combinations and conspiracies alleged be declared to be illegal and violative of the Sherman Anti-Trust Act; (2) that the defendants be perpetually enjoined from further engaging in or carrying out the restraints and conspiracy alleged; (3) that the defendant medical societies be perpetually enjoined from refusing to take into their membership, and from expelling or threatening to expel from their membership any physician because of his cooperation in medical care plans other than those sponsored or approved by the defendants; (4) that defendant medical societies, on application or request therefor by any such physician, shall reinstate as a member in good standing any physician expelled from membership because of his cooperation in a medical care plan other than those sponsored or approved by the defendants; (5) that the defendants be perpetually enjoined from persuading or inducing or attempting to persuade or induce hospitals to discriminate in the use of their facilities against physicians or patients cooperating or associated with medical care plans other than those sponsored or approved by the defendants; (6) that the defendants be perpetually enjoined from persuading or inducing or attempting to persuade or induce physicians not to cooperate in medical care plans other than those sponsored by the defendants; (7) that the defendants be perpetually enjoined from suggesting, advocating or agreeing that physicians should refuse to treat patients who are associated with medical care plans other than those approved or sponsored by the defendants, or to discriminate against such patients with respect to fees charged for medical services, or discriminate against such patients by requiring them to pay cash for medical services or refuse to supply itemized statements to such patients showing the medical services rendered and the fees charged therefor; (8) that defendants be perpetually enjoined from the publication or dissemination of false or disparaging publicity concerning medical care plans other than those sponsored or approved by the defendants; (9) that the defendants be perpetually enjoined from advocating, inducing or agreeing that physicians who are members of defendant medical societies should refuse to consult in the diagnosis, care or treatment of patients of physicians cooperating in medical care plans other than those sponsored or approved by the defendants, or of physicians who are not members of defendant medical societies; (10) that the defendant "medical associations" be perpetually enjoined from refusing to give approval to any medical care plan on the ground that such plan is controlled or sponsored by a commercial organization, or that such plan provides for medical care of patients having incomes above any given amount, or that such plan would compete with one or more other medical care plans approved or sponsored by the defendants; (11) that defendant "medical societies" be required to advise in writing all their component county medical societies, and to publish a statement in *Northwest Medicine*, that it no longer be the policy of such medical societies to do those things which, as alleged, they have combined and conspired to do; (12) that the plaintiff have such other and further relief as the court may deem just and proper, and (13) that the plaintiff recover its costs.

Complete Service Bureau, a nonprofit corporation, George Roy Stevenson, Chester J. Antos, and Robert L. Williams, Plaintiffs v. San Diego County Medical Society, a nonprofit corporation, Robert J. Prentiss, Hiram D. Newton, W. H. Geistweit Jr., William C. Black, Morton N. Carlile, E. Minton Fetter, O. S. Harbaugh, George Hartlye Jr., Ralph L. Hoffman, Wilton M. Lewis, J. D. MacPherson, Robert McIver, Thomas F. O'Connell, D. H. Werden, Francis E. West, Blythe W. Pahl, John Doe Nos. 1 to 20 respectively and inclusively, John Doe Company, a corporation, Richard Roe Company, a corporation, and Peter Woe Company, a corporation, Defendants.

Filed in the Superior Court of the State of California in and for the County of San Diego, Oct. 16, 1948.

The individual plaintiffs in this case are physicians associated with Complete Service Bureau, a nonprofit corporation operating a medical care plan. The individual defendants designated by their true names are members of the San Diego County Medical Society.

The complaint, nineteen pages in length, alleges, as a prelude, that the San Diego County Medical Society, the California Medical Association and the American Medical Association constitute a medical trust which connives to promulgate and enforce interlocking rules and regulations to control the practice of medicine and influence the operation of hospitals in the County of San Diego, Calif., and elsewhere. Additionally it is alleged that since 1937 the San Diego County Medical Society, in pursuance of a conspiracy, has closed its membership to all physicians engaged in service to the members of Complete Service Bureau and that it has sought to visit on such physicians complete business and social ostracism, complete restriction of consultation with society members, complete barring of such physicians and their patients from the major hospitals of San Diego County and to restrict them in the exercise of freedom of speech and freedom of contract.

The San Diego County Medical Society, the complaint continues, in or about the year 1937 expelled from its membership plaintiff Stevenson solely because of his connection with Complete Service Bureau and this action was affirmed by the California Medical Association on appeal. In or about the month of July 1948, it is alleged, the other named individual plaintiffs applied for membership in the society and their applications were rejected. One of the requirements for membership, the complaint states, is that the applicant must be recommended by two active members in good standing but that members have refused to sign the applications of physicians who are affiliated with Complete Service Bureau.

In further pursuance of the conspiracy alleged, the complaint charges that the defendants during the year 1947 and thereafter have attempted to poison the minds of the public against nonmembers by causing to be published and circulated paid advertisements in current editions of the San Diego County Telephone Directory of the Pacific Telephone & Telegraph Co., wherein most of the "member doctors are designated as members of San Diego County Medical Society" and in which appears statements intended falsely to convey to the public that nonmembers are not qualified to practice medicine, do not possess professional qualifications and moral character and do not conform to standards insuring the highest possible quality of service to the public.

Furthermore, it is charged, the defendants during the year 1947 and thereafter, have by word of mouth caused to be circulated by themselves and by society members and by nurses and other employees, and by members of their families, remarks in belittlement and derogation of nonmembers, frequently referring to them as "quacks" and designating their groups as "outfits" and characterizing the prepaid medical plan as a "scheme." The medical alleged trust and the defendants, the complaint continues, endeavor to shield their members from exposure and liability in case of malpractice and members of the San Diego County Medical Society consistently decline to appear as expert witnesses in court actions against other members of the society.

It is the custom of the medical trust and its members, it is charged, to recommend to hospital organizations operating in California a form of by-laws, rules and regulations for medical staff as approved by the American College of Surgeons, which contains an article on membership providing that applicants for membership on the medical staff of such hospitals shall be graduates of an approved medical school, legally licensed to practice in California, *qualified* for membership in the local medical society and practicing in the community or within a reasonable distance of the hospital. The complaint charges that the defendants further in pursuance of a conspiracy has induced the Quintard Hospital Corporation of San Diego to modify this recommended form by limiting members on its staff to members of the San Diego County Medical Society.

By reason of the activity of the defendants, the complaint charges, the Complete Service Bureau has had considerable difficulty in obtaining physicians to function in connection with its medical care plan, although the bureau has advertised for such physicians through various agencies existing throughout the United States and through advertising in periodicals circulated among physicians.

The complaint further charges that the Quintard Hospital Corporation, maintaining a hospital in San Diego, for several years extended staff courtesies to the individual plaintiffs and has accorded to members of Complete Service Bureau admission to the hospital and full hospital services. The hospital named, it is brought out in the complaint, was accepted for registration by the Council on Medical Education and Hospitals of the American Medical Association, June 19, 1948, but that the defendants have persuaded the management of the hospital corporation that in order to comply with the requirements of the American Medical Association and to maintain the recognition already given, it will be necessary to deny privileges to plaintiffs and to members of Complete Service Bureau. A letter was received from the Quintard Hospital Corporation, the complaint continues, advising the plaintiffs that in order to comply with the requirements set forth by the American Medical Association it will be necessary for the hospital to deny privileges to Complete Service Bureau.

The complaint charges that Complete Service Bureau has suffered and will suffer actual damages in the sum of $25,000 and each individual plaintiff damages in like amount. The complaint prays for a judgment for double the amount of actual damages and requests an injunction requiring the defendant San Diego County Medical Society to admit to membership the individual plaintiffs and all other qualified physicians affiliated with them, and to refrain from suspending or expelling them for any affiliation or participation with any prepaid medical group conducting its business in the manner in which Complete Service Bureau has been acting. An injunction is asked against all defendants restraining them from any and all acts intended to and tending to hinder and obstruct Complete Service Bureau in the conduct of its business and to obstruct the individual members of such bureau and physicians serving them in free availability of medical and hospital services in the market. The plaintiffs ask to recover their costs and to have all other proper relief.

Washington Letter

(From a Special Correspondent)

Nov. 7, 1948.

Supreme Court Hears Arguments in Urbeteit and Kordel Cases

Arguments in the Urbeteit and Kordel cases, both of which involve implements for self treatment which the federal government claims to be worthless, were heard by the U. S. Supreme Court October 13-14. Outcome of the 2 cases is expected to depend on the Court's interpretation of the word "accompany"; that is, whether or not the Food and Drug Act was violated in view of the fact that, in many of the interstate shipments of Urbeteit's "sinuothermic" machine and Kordel's drug remedies, the allegedly false and misleading literature describing the products was mailed separately from the merchandise. Government counsel argued that Congress, in passing the Food and Drug Act, did not intend that such descriptive material must be shipped in the same carton as the product for the federal law to be involved. Opposing counsel took a contrary view. How long it will be before the Supreme Court reaches a decision cannot be foretold.

Chlorine Dioxide Likely to Replace Agene® in Flour Milling

Following a conference held recently in Washington, the Food and Drug Administration is working on, and probably will issue within a few weeks, revised standards for manufacture of flour the principal change in which will be substitution of chlorine dioxide for nitrogen trichloride (agene®) as a bleaching agent. Evidence was presented at the conference, attended by representatives of federal law enforcement agencies, the milling and drug industries and scientists familiar with the toxicity of agene,® that the proposed substitute is both safe and practical. Among those who were heard at the conference sponsored by the Food and Drug Administration was Sir Edward Mellanby, who in 1946 demonstrated the injurious effect on dogs of white flour bleached with nitrogen trichloride (See The Journal of Nov. 22, 1947).

Women Physicians to Intern in Naval Hospitals

Its ranks now open to women, the Regular Navy is seeking to fill twenty-five newly created positions for interns in naval hospitals. In addition, twenty dietitians and two physical therapists are needed for the Medical Service Corps, to start with the rank of ensign. Women interns will be commissioned as lieutenants (junior grade) in the Naval Reserve and, on completion of eight months' training, they will be qualified to take the professional examinations for the Regular Navy. Details of another procurement program under which civilian woman physicians may apply directly for the Regular Navy will be announced later.

Scientist Mobilization Committee Formed

A special committee on mobilization of scientific man power has been announced by the National Military Establishment. Chairman of the group, whose first meeting was held in Washington, October 13-14, is Irvin Stewart, president of West Virginia University. Its formation was at the suggestion of Vannevar Bush, retiring chairman of the Research and Development Board.

First Displaced Persons to Arrive in the United States

The first immigrants under the Displaced Persons Act have arrived in this country. Among them there is expected to be a small proportion of physicians, dentists and nurses, according to the Washington offices of the International Refugee Organization. Of 340,000 displaced persons whose occupational skills have been classified, 1,150 men and 458 women are listed as physicians and surgeons. In addition, 43 men and 25 women are classified as pediatricians; 35 men and 17 women as ophthalmologists; 294 men and 462 women as dentists; 21 men and 2,566 women as nurses and nurses' aides; 349 men and 380 women as pharmacists; 300 men and 36 women as veterinarians, and 15 men and 21 women as dietitians. In addition, there are approximately 350 dental technicians and mechanics, 85 medical laboratory technicians, 70 opticians, 300 physical therapists and 60 x-ray technicians. The International Refugee Organization is working with various voluntary agencies to facilitate sponsored entry of professional and subprofessional workers and their admission to practice of their vocations in the various states.

Tri-Service Specialty Board Defers Action on Candidates

In anticipation of final recognition of the American Board of Preventive Medicine and Public Health within the next few months, the Interim Board of Preventive Medicine and Public Health took no action on applications for certification at its meeting October 15. The interim group, representing the Army, the Navy and the U. S. Public Health Service, plans to disband as soon as the newly organized national board, whose trustees met in Chicago last month, achieves formal recognition by the Advisory Council on Medical Specialities. Dr. Ernest L. Stebbins, secretary of the American Board of Preventive Medicine and Public Health and chairman of the interim triservice body, presided over the October 15 meeting.

Advisory Health Council

Recommendations for research grants made by its various study sections were to be laid before the National Advisory Health Council at its meeting October 22 at the National Institutes of Health. This was the final session for two members, whose terms expire at the end of this year. They are Drs. Gordon Fair and Harry Mustard.

Hoover Commission Schedules Hearings for Professional Groups

Representatives of the American Medical, Hospital, Dental and Public Health Associations were scheduled to appear before the Hoover Commission's committee on medical and hospital services October 21-22 to explain their ideas for improving these services as administered by the federal government.

Radioisotope Facilities

The F. H. Martell Co., contractors, has been announced by the U. S. Public Health Service as low bidders for the contract to build a radioisotope facilities building to serve the clinical research hospital and laboratories now under construction at the National Institutes of Health, Bethesda, Md.

Coming Medical Meetings

American Medical Association Interim Session, St. Louis, Municipal Auditorium, Nov. 30-Dec. 3. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Conference of State Secretaries and Editors, St. Louis, Hotel Statler, Nov. 28-29. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

National Medical Public Relations Conference, St. Louis, Hotel Statler, Nov. 27. Mr. Lawrence W. Rember, 535 N. Dearborn St., Chicago 10, Director.

American Academy of Dermatology and Syphilology, Chicago, Palmer House, Dec. 5-9. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, Secretary.

American Academy of Pediatrics, Atlantic City, Chalfonte-Haddon Hall, Nov. 20-23. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American Association of Railway Surgeons, Chicago, Nov. 21-23. Dr. Raymond B. Kepner, 547 W. Jackson Blvd., Chicago 6, Secretary.

American Public Health Association, Boston, Nov. 8-12. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary

American Society of Tropical Medicine, New Orleans, Roosevelt Hotel, Dec. 5-9. Dr. Frederick J. Brady, National Institute of Health, Bethesda 14, Maryland, Secretary.

Association for Research in Nervous and Mental Diseases, New York, Waldorf-Astoria Hotel, Dec. 10-11. Dr. Clarence C. Hare, 700 W. 168th St., New York 32, Secretary.

Eastern Section, American Federation for Clinical Research, Philadelphia, Temple University School of Medicine, Dec. 4. Dr. J. Edward Berk, Temple University School of Medicine, Philadelphia, Chairman.

International College of Surgeons, U. S. Chapter, St. Louis, Kiel Auditorium, Nov. 16-19. Mr. Ralph E. Osborne, 1516 Lake Shore Drive, Chicago, Business Secretary.

Puerto Rico, Medical Association of, Santurce, Dec. 10-12. Dr. J. Basora Defillo, Box 3866, Santurce, Secretary.

Radiological Society of North America, San Francisco, Dec. 5-10. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Southern Psychiatric Association, Dallas, Texas, Hotel Adolphus, Dec. 6-7. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southern Surgical Association, White Sulphur Springs, W. Va., Dec. 7-9. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Western Surgical Association, St. Louis, Dec. 2-4. Dr. Warren H. Cole, 1853 W. Polk St., Chicago 12, Secretary.

GOVERNMENT SERVICES

ARMY

JAPANESE RESEARCH IN THE SOCIAL SCIENCES

The Department of the Army's Civil Affairs Division has announced that five American educators are en route to Tokyo, Japan, on ninety day assignments to assist General MacArthur's headquarters in promoting the expansion of Japanese research in the social sciences. The five educators will appraise current social science research and act as a board of consultants to Japanese scholars and scientific organizations in formulating plans for personnel training, long range research projects and organizational programs. The mission will also advise officials in planning future assistance and encouragement to be extended to social science research activities in Japan. Members of the mission are: Glenn T. Trewartha, chairman, department of geography, University of Wisconsin, Madison, Wis.; Luther W. Stalnaker, professor of philosophy, Drake University, Des Moines, Iowa; George K. Brady, professor of English, University of Kentucky, Lexington; Edwin O. Reischauer, associate professor of far eastern languages, Harvard University, Cambridge, Mass., and Charles E. Martin, professor of international law and political science, University of Washington, Seattle.

SENTENCES FOR WAR CRIMES

The Department of the Army has released a recapitulation of sentences involving war crimes defendants in Germany. Of the 1,672 sentences originally imposed, 1,090 were approved on review and 69 were disapproved; there were 256 acquittals and 255 sentences were reduced. Of the 426 death sentences adjudged, 299 were approved; of the 199 life sentences, 139 were approved on review; of 10 thirty year sentences, 6 were approved and the other 4 were reduced; of the 25 year sentences adjudged, 2 were disapproved and the other 19 adjudged were much reduced, and so on with the lesser sentences adjudged. The total number of sentences approved as adjudged was 1,090, the disapproved was 69, the acquittals 256, and the reduced sentences numbered 255.

TRAINING IN CIVILIAN INSTITUTIONS

The Surgeon General's Office announced October 12 that forty more Medical Department officers had been accepted for training in civilian institutions. This training includes internships for the young officers and for others special courses in poliomyelitis and surgery. The list of officers comprised four colonels, two lieutenant colonels, one major and thirty-three first lieutenants.

INSTITUTE OF PATHOLOGY EXHIBITS

The Institute of Pathology presented an exhibit entitled "The General Practitioner in the Atomic Age," at the centennial meeting of the Medical Society of the State of Pennsylvania at Philadelphia October 4-7. The six panel exhibit was planned to bring to the attention of general practitioners clinical conditions and damage to both animate and inanimate objects, a possible plan for management of catastrophies and some recognized methods of treatment.

The institute presented an exhibit at the meeting of the American Society of Clinical Pathologists in Chicago October 10-15, comprising eight panels explaining the activities of the American Registry of Pathology.

NAVY

SPECIAL COURSE FOR RESERVE OFFICERS

A course of instruction in the medical aspects of radioactive isotopes and special weapons will be conducted at the Naval Medical School, Bethesda, Md., from December 6 through December 10. The course is primarily for the benefit of inactive reserve medical officers. The instructors will be outstanding men in their specialties. Inactive reserve medical officers who desire to attend this course should submit a request to the commandant of their local naval district prior to November 15. The facilities available make it necessary to restrict attendance to 200 officers. Sleeping quarters will be available for many of those who wish such accommodations.

NOMINATED FOR POSTGRADUATE INSTRUCTION

The following medical officers were nominated early in October for courses in postgraduate instruction: Lieut. John T. Egan of Jamaica, L. I., N. Y., to a residency in obstetrics and gynecology at the Naval Hospital, St. Albans, N. Y.; Lieutenants (jg) Paul G. Bamberg, M.C.R., of Boston, to a residency in general practice, Naval Hospital, Chelsea, Mass.; Robert C. Kessler, M.C., of Auburn, N. Y., to a residency in general practice, Naval Hospital, Portsmouth, Va., and John H. Young, M.C., of Dayton, Ohio, to a residency in psychiatry at the Naval Hospital, Bethesda, Md.

PERSONALS

The following Medical Reserve Corps officers have reported for their first active duty: Lieutenants Timothy F. Lally of San Francisco; (jg) John E. Aiken of Los Angeles; Louis E. Beckham Jr., of Tuscaloosa, Ala., and Robert R. Gillespy Jr., of Garden City, N. Y.

Capt. James J. Hayes of Brooklyn, and Lieutenants (jg) John S. Graettinger of Ontario, Calif., and Ramon A. Mouton of New Orleans have transferred from the Medical Corps Reserve to the Regular Navy.

Comdr. Thomas E. Cone Jr., M.C.R., of Cranston, R. I., is being recalled to active duty and ordered to postgraduate instruction under the new Navy Graduate Medical Training Program. Capt. Raymond J. Mansfield, M.C.R., of Healdsburg, Calif., and Lieut. (jg) Forrest M. Nelson, M.C.R., of Austin, Texas, have voluntarily been recalled to active duty.

Comdr. George H. Davis, M.C., has been assigned to the Naval Medical Center, Bethesda, Md., as a resident in radiology.

NEW NAVY INTERNS

The Bureau of Medicine and Surgery announced as of October 13 that twenty-five additional medical school graduates have accepted commissions as lieutenants (jg) in the Medical Corps Reserve under the Navy's Medical Intern Training Program for internships in civilian institutions. On the completion of the period of internship they will serve on active duty in the Navy.

LEPROSY CONTROL IN THE PACIFIC ISLANDS

Lieutenant Jack W. Millar, M.C., U.S.N., of Palo Alto, Calif., has volunteered for assignment on Tinian Island in the Pacific to start the first leprosy control effort in the Pacific Trusteeship Territory. The Navy is completing a temporary leprosarium on Tinian Island with facilities for treating 100 patients, natives of the Carolines, Marianas, Marshalls, Palaus and Yap. In all, there are about 50,000 natives on these islands, and, according to the Associated Press, Dr. Millar estimates that the number of lepers among them exceeds 500 and may be as many as 1,000. Tinian Island, which has no native population, is now occupied by a small naval force. Dr. Millar will be assisted in this work by two naval medical corpsmen.

VETERANS ADMINISTRATION

SPECIAL HOMES FOR PARAPLEGICS

The Veterans Administration, Washington, D. C., states that a veteran of war or peacetimes service with a permanent, total, service-connected disability due to a disease or injury of the spinal cord, which results in paralysis of the legs and lower part of the body may qualify for federal aid to acquire a home specially designed for wheel chair living. Eligible veterans will receive a federal grant of not more than 50 per cent of the cost of the home or a maximum of $10,000 with which to buy or build a new home or to remodel an existing home for their requirements. The grant also may be used to pay off the indebtedness on such a special home already acquired by an eligible veteran.

LIFE INSURANCE FOR VETERANS

National Service Life Insurance has been available since Oct. 8, 1940, to persons serving in the armed forces. However, those ordered to temporary active duty for thirty days or less do not qualify by virtue of that service. Veterans are entitled to retain their National Service Life Insurance after discharge, and those who served between Oct. 8, 1940, and Sept. 2, 1945, may (subject to certain health requirements) take out new insurance even though they held none while in service. This group also may increase the amount of their government insurance at any time up to the $10,000 maximum. The premium rates on National Service Life Insurance are low because all administrative costs and expenses resulting from claims traceable to the extra hazards of military or naval service are borne by the government and are paid by separate appropriations. There are no restrictions as to residence, travel, occupation or service in the armed forces. National Service Life Insurance is mutual insurance, and premiums and interest earned from invested funds are carried in a Treasury trust fund. Dividends will be payable as earned and authorized by the Administrator of Veterans Affairs. For a small additional premium, there may be added to any policy a total disability rider which provides monthly payments to the insured while he is totally disabled for six consecutive months or longer. National Service Life Insurance carries no restriction as to designation of beneficiaries. The insured may name any person or firm or his estate or other legal entity to receive the proceeds of his insurance.

CONTRACT FOR HOSPITAL AT SEATTLE

The contract for the construction at Seattle of a 300 bed general medical and surgical hospital for the Veterans Administration has been awarded. The general construction contract was awarded the low bidder for $6,077,320; elevators and dumbwaiters will be installed for an additional $234,319.

PERSONALS

Dr. Roy O. Hawthorne has been promoted to chief medical officer at the veterans hospital in St. Petersburg, Fla.

Dr. Clarence R. Miller has been assigned as manager of the Veterans Administration Hospital at Jackson, Miss., to succeed Dr. J. Ralston Wells, who will be in charge of the Veterans Hospital at Dallas, Texas. Dr. Miller is a veteran of World War I, formerly served in the U. S. Public Health Service, and for many years has been in the Veterans Administration.

PUBLIC HEALTH SERVICE

MICROBIOLOGICAL INSTITUTE

Surgeon General Scheele has appointed Dr. Victor H. Haas director of the new Microbiological Institute which has been established in the National Institutes of Health. The following units of the National Institutes of Health have been assigned to the Microbiological Institute: the Division of Infectious Diseases, the Division of Tropical Diseases and the Biologics Control Laboratory, which, on transfer November 1, will be renamed respectively the Laboratory of Infectious Diseases, the Laboratory of Tropical Diseases and the Laboratory of Biological Control. The Rocky Mountain Laboratory at Hamilton, Mont., which formerly was under the Division of Infectious Diseases, will operate as a separate laboratory under the general supervision of the director of the Microbiological Institute. The institute also will conduct studies on the transmission, control and prevention of infectious diseases and fundamental research on the growth requirements, metabolism and conditions of survival of micro-organisms as related to public health.

Dr. Haas joined the Public Health Service in 1932, the year in which he was graduated from the University of Cincinnati School of Medicine. During the war he was in charge of the disposition of medical forces connected with the construction of the Stilwell Road from India to Burma and China, and for this work was awarded the Legion of Merit. In 1947 he was named chief of the Subdivision of Malaria in the Division of Tropical Diseases, National Institutes of Health.

DETAILED INFORMATION ON CANCER

A survey sponsored by the National Cancer Institute, the Maryland State Health Department and the American Cancer Society will endeavor to obtain detailed information on cancer and an evaluation of the effectiveness of cancer control technics at the local health unit. The survey will be made in Frederick, Hartford, Montgomery and Washington counties in Maryland, in which counties cards have been distributed to physicians and hospitals for reporting the name, location and type of each case of cancer. This information will be kept confidential. A card is also filled out and returned to the county health department for each new patient with cancer, and a case worker will call on the patient and his family. Completed case histories will be correlated with those of other patients with cancer. The survey will evaluate also the adequacy of existing hospital and medical personnel and the effectiveness of nurses in case finding and follow-up.

NATIONAL INSTITUTES OF HEALTH

Surgeon General Scheele has announced the assignment of additional laboratories to the Experimental Biology and Medicine Institute which is a part of the National Institutes of Health. On October 15, the Laboratory of Physical Biology was assigned to the Experimental Biology and Medicine Institute, the designation of the Division of Physiology was changed to Laboratory of Biochemistry and Nutrition, the designation of the Chemistry Laboratory was changed to Chemistry and Chemotherapy, and the designation of the Pathology Laboratory was changed to Pathology and Pharmacology. The Director of the Institute of Experimental Biology and Medicine is Dr. William H. Sebrell.

PERSONALS

Dr. Ralph W. G. Wyckoff of the National Institutes of Health, Bethesda, Md., has gone to Europe to accept an honorary degree from the Faculty of Medicine of the Masaryk University at Brünn, Czechoslovakia, in recognition of his work in the application of physics to biology and medicine.

Dr. Robert J. Anderson has been appointed as medical director and chief of the Tuberculosis Control Division to succeed Dr. Francis J. Weber, who will do postgraduate work at Johns Hopkins University.

Surgeon Charles C. Shepard left for Sweden September 12 for a course of special training in chemical biophysics at Uppsala University under the tutelage of Prof. Arne Tiselius, a widely known investigator in this field. This inaugurates a new policy for additional training of young research officers at the National Institute of Health.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CONNECTICUT

Personal.—Dr. Edward B. Sinclair, New Haven, has been appointed Crippled Children physician in the State Department of Health. A graduate of Yale University School of Medicine in 1935, Dr. Sinclair, after discharge from the army in 1946, was medical consultant for vocational rehabilitation at the Veterans' Administration office, Providence.

The Care of the Patient.—Sponsored by the Connecticut State Medical Society, a Committee for the Improvement of the Care of the Patient was formed at a recent meeting in New Haven. The committee includes Drs. Katherine J. Edgar, Bridgeport; Joseph A. Fiorito, New Haven, and D. Dillon Reidy, Hartford, for the state medical society; Irma Bieheusen, New Haven; Helen M. Cullen and Agnes Ohlson, Hartford, for the State Nurses' Association; William J. Donnelly, Greenwich; Leon H. French, Waterbury; Richard J. Hancock, New London, and Hiram Sibley, New Haven, for the Connecticut Hospital Association.

DISTRICT OF COLUMBIA

Clinical Cancer Research.—Dr. Roy Hertz, assistant professor of medicine at George Washington University School of Medicine, has been named chairman of a committee to develop and direct a joint program of clinical cancer research sponsored by the medical school and the National Cancer Institute. Other members of the committee are Drs. Brian Blades, Thomas M. Brown, Calvin T. Klopp, Thomas M. Peery, J. Keith Cromer and Paul K. Smith, Ph.D. The cooperative program is financed by the National Cancer Institute, the American Cancer Society and private sources. Three initial studies are under way:

1. Endocrine and metabolic aspects of cancer of the breast, prostate, uterus, ovaries and testes.
2. Nutritional aspects of cancer of the gastrointestinal tract. The first study concerns the metabolism of vitamin A.
3. Metabolic aspects of nitrogen mustard therapy in lymphoid diseases. A clinical laboratory for these studies has been established at the new George Washington University Hospital, and a ward will be set up shortly. Further studies, as well as the patients to be admitted, will be determined by the directing committee, with the advice of the tumor board of Warwick Clinic. The National Cancer Institute laboratories at Bethesda, Md., will be available also for studies that require more extensive technical facilities.

GEORGIA

Fifty Years in Practice.—At a meeting of the Council of the Medical Association of Georgia September 22, a proposal was approved to award appropriate certificates and lapel buttons to all reputable physicians of the state who have completed fifty years in the practice of medicine. The responsibility for selecting these physicians was placed on the county medical society. Awards will be presented at the Centennial Session of the association, May 10-13, 1949.

KENTUCKY

Dr. Brown Given Distinguished Service Medal.—The Distinguished Service Medal, awarded annually by the Kentucky Medical Association, was presented to Dr. J. Samuel Brown, Ghent, at the recent annual meeting in Cincinnati. He was nominated by the Tri-County Medical Society for having rendered the most outstanding service not only during the current year but in years past. Dr. Brown has practiced in Carroll County for more than fifty-five years.

LOUISIANA

Graduate Course on Neoplastic Diseases.—A graduate course on neoplastic diseases will be presented in the Hutchinson Memorial Building Auditorium, Tulane University of Louisiana Division of Graduate Medicine, New Orleans, November 15-17, in conjunction with the Orleans Parish unit and the Louisiana State Divisions of the American Cancer Society. A tumor clinic will be held Wednesday afternoon in Miles Amphitheater, Charity Hospital. On the evening of November 15 the first annual lectureship of the Louisiana State Division of the American Cancer Society will be presented by Dr. Vernon David, Chicago, speaking on "The Local Spread of Carcinoma of the Large Bowel and Its Bearing on Prognosis and Treatment," and by Dr. John R. McDonald, Rochester, Minn., speaking on "The Smear Technic as an Aid in the Diagnosis of Malignancy."

MAINE

Rockefeller Gives Land to Laboratory.—Thirty acres of land across the road from the main laboratory unit have been given to the Roscoe B. Jackson Memorial Laboratory at Bar Harbor by John D. Rockefeller Jr. It will be used for a group of units to house visiting scientists who work at the laboratory each summer.

The Lancaster Course in Vision.—The Foundation for Vision has decided to repeat its course in the basic subjects of ophthalmology under the supervision of the Ophthalmological Study Council, which is sponsored by the foundation. The next course will use the facilities of Westbrook Junior College in Portland, Maine. It is to be known as the Lancaster Course in honor of Dr. Walter B. Lancaster, director of the previous courses, who will be succeeded by Dr. Parker Heath, clinical professor of graduate ophthalmology at Harvard Medical School.

MARYLAND

Friedenwald Lecture.—Dr. Frank H. Lahey, Boston, on October 14 gave the third annual Dr. Julius Friedenwald Memorial Lecture at the University of Maryland School of Medicine, Baltimore, on "Gastric Surgery." The Friedenwald Lecture was established at the university in 1941.

Dr. Longmire Goes to California.—Dr. William P. Longmire Jr., associate professor of surgery, Johns Hopkins University School of Medicine, Baltimore, has been appointed professor of surgery in the Medical School, University of California at Los Angeles. Dr. Longmire received his M.D. degree at Johns Hopkins in 1938.

MICHIGAN

Personals.—Dr. Walter J. Wilson Sr. has been made emeritus professor of clinical medicine at Wayne University College of Medicine, Detroit.——Dr. Harold B. Rothbart, instructor in clinical pediatrics, Wayne University College of Medicine, Detroit, has been named president of the Detroit Pediatric Society for the current year.

Public Health Conference.—The annual Michigan Public Health Conference will be held at the Pantlind Hotel, Grand Rapids, December 1-3. Emphasis will be placed on Michigan programs, and a symposium type of session will be featured. After adjournment of the conference on Friday the Michigan School Health Association will meet.

Cancer Institute Affiliates with Wayne University.—The Detroit Institute for Cancer Research has been formally affiliated with the Wayne University College of Medicine, Detroit. Under the plan, appointments to the scientific staff of the institute will be made on recommendation of its scientific director when such recommendations bear the endorsement of the university faculty. The dean of the college will be a member of the executive committee of the board of trustees of the institute, and the scientific director of the institute will be a member of the administrative committee of the college.

MISSOURI

St. Louis' Silver Jubilee Dinner.—St. Louis University School of Medicine at a dinner October 29 at the Missouri Athletic Club honored those who have served twenty-five years or more as instructional officers, giving each one a citation and a replica in silver-plated bronze of the seal of St. Louis University. Father Alphonse Schwitalla, dean, presided. Dr. Alphonse McMahon, associate professor of internal medicine, gave the response for the jubilarians. The dinner address was given by Dr. Morris Fishbein, Chicago, on "Ideals of American Medicine." The jubilarians were: Drs. Franklin H. Albrecht, Leo Bartels, Irving H. Boemer, Ralph L. Cook, Joseph P. Costello, Oswald P. J. Falk, Florent E. Franke, George T. Gafney, William J. Gallagher, John Green, John F. Hardesty, Walter E. Hennerich, Joseph L. Hutton, Vincent L. Jones, Alver H. Kerper, Paul F. Kistner, Ellsworth Kneal, George H. Koenig, Alexander J. Kotkis, Paul Lowenstein, William H. Leudde, Benjamin F. May, Alphonse McMahon, Albert J. Motzel, Charles A. Neumann, Carl A. Powell, Rudolph V. Powell, Hugo Reim, Linus M. Ryan, Harry Sandperl, LeRoy Sante, Robert E. Schlueter, Alfred O. Shaklee, Charles F. Sherwin, Edward C. Spitze, John W. Stewart, Edward A. Dorsy, Ph.D., and Wendell H. Griffith, Ph.D.

MONTANA

Open Medical Research Center.—Montana's first medical research center, established by the Western Foundation for Clinical Research, opened in September in a remodeled wing of a local hospital in Great Falls. The foundation has received a $22,500 grant from the National Institute of Health, which has enabled it to start on its first project. The center will initially study methods of preventing or relieving abnormal accumulation of fluids in heart, blood vessels and kidney disease, under the direction of Dr. Ferdinand R. Schemm, who has been designated by the National Institutes of Health as chief investigator of the project, serving without remuneration. Research and dietetic laboratories and a metabolic unit with rooms for about 12 patients who will be under study make up the center. The Western Foundation, according to John D. Stephenson of Great Falls, secretary-treasurer, was established in the hope that worth while research could be undertaken in the Northwestern section of the United States using qualified local personnel.

NEBRASKA

Dr. Davis to Head Department of Surgery.—Dr. Herbert H. Davis, a member of the department of surgery at the University of Nebraska College of Medicine, Omaha, has been appointed chairman of the department, succeeding Dr. J. Jay Keegan, professor of neurologic surgery, who wished to be relieved of administrative duties. Dr. Davis is a graduate of Johns Hopkins University School of Medicine, Baltimore, 1920, and is one of the founding members of the American Board of Surgery. His father, the late Dr. Bryon B. Davis, was at one time chairman of the department.

NEW MEXICO

State Medical Election.—At the annual meeting of the New Mexico Medical Society, Philip L. Travers, Santa Fe, was installed as president, James W. Hannett, Albuquerque, was chosen president-elect, Harold L. January, Albuquerque, secretary-treasurer and John F. Conway, Clovis, delegate to the American Medical Association, with William R. Lovelace as alternate.

NEW YORK

Medical Advisory Board for Boxing Commission.—To make boxing and wresting less hazardous, New York has enacted a law creating a nine man medical advisory board to the state boxing commission under the chairmanship of Dr. Frank R. Ferlaino, New York. New standards and regulations for examination before and after bouts will be formulated by the advisory board. Dr. Ferlaino reports that in 1946 there were 11 deaths in the ring, in 1947, 9, and as of September 27, 1948, 12. Dr. Ferlaino is a graduate of the John Hopkins Medical School, is an attending physician at the New York Post Graduate Medical School and Hospital, has specialized in the relation of trauma to disease in industry and is consulting physician to the General Motors Corporation.

Laboratory Training for Pathologists.—Pathologists preparing for a career in diagnostic laboratory work in New York State may receive training in a program sponsored by the New York State Department of Health. Experience in pathology, bacteriology, biochemistry and other laboratory fields is afforded in this division and in cooperating institutions in Albany and in New York City. One year appointments are open to physicians with graduate training. The program is approved by the American Board of Pathology. Candidates must be United States citizens and graduates of a medical school approved by the American Medical Association. They need not obtain a license to practice medicine in New York State, but must be eligible to take the examination for license. A stipend is granted to trainees. Inquiries should be directed to the Division of Laboratories and Research, State Department of Health, Albany 1.

New York City

Symposium on Viral Infections.—A symposium on pathogenesis and pathology of viral infections will be held by the section on microbiology of the New York Academy of Medicine on Tuesday evening and Wednesday afternoon and evening of December 14 and 15, with Dr. John G. Kidd as chairman.

Hospital News.—Cornerstone for the new Shirley Joyce Katz Pavilion of the Jewish Sanitarium and Hospital for Chronic Diesases, Brooklyn, was laid September 19 and will be completed next spring. The new building, the fourth on the hospital grounds, will add 350 beds and an entire floor for medical research on poliomyelitis and chronic diseases. Two wings will be devoted to the care of children suffering from poliomyelitis and rheumatic heart conditions.

Transportation Service for Premature Infants.—The departments of hospitals and health of New York City are instituting a free transport service for premature babies. A special ambulance with portable heated incubators and oxygen and staffed by nurses who have been trained in the care of prematurely born infants is provided. Requests for transportation of premature babies are made to the Maternity and Newborn Division, Department of Health, 125 Worth Street, WOrth 2-6900. A similar service has been used successfully for a number of years in Chicago and Baltimore.

Sharp Increase in Tuberculosis.—The New York Tuberculosis and Health Association has reported a 12 per cent increase in the number of new cases of tuberculosis in New York City during the first nine months of 1948. The report showed 6,433 new cases registered with the department of health between January 1 and September 30, an increase of 666 over the same period in 1947. A total of 2,445 deaths from tuberculosis was recorded in the city, which was an increase of 126, or 5 per cent, over the number reported for the similar period of 1947. Increases were noted in every borough but the Bronx, with the highest rate recorded for Manhattan. Of 18,000 known cases of tuberculosis in the city, a total of 7,959 was segregated either in the hospitals within the city or in sanatoriums out of town. The number hospitalized within the city, 5,485, was 11 per cent greater than a year ago on the same date. The number of patients attending tuberculosis clinics, 4,820 on September 30, was 8 per cent more than a year ago, and the number under the care of private physicians, 3,965, showed a decrease of 6 per cent. The tuberculosis death rate for the first nine months of 1948 was 40.4 per 100,000 population as contrasted with the rate of 38.9 for the same period last year. In Manhattan the rate increase was double that recorded for the city as a whole.

OHIO

Personal—Dr. Richard L. Meiling, assistant professor of obstetrics and gynecology at Ohio State University College of Medicine, Columbus, has been named a medical consultant to the committee studying the organization of the U. S. security program for the Hoover Commission. Dr. Meiling aided in planning the Army's medical air evacuation program during World War II.

Dr. Toomey on Leave of Absence.—Dr. John A. Toomey, Cleveland, has left his duties as director of the contagious department at the City Hospital and professor of clinical pediatrics and contagious diseases at Western Reserve University School of Medicine for a sabbatical leave to rest and do private practice in Miami. He is replaced by Dr. Morris Schaeffer, who is acting director of the contagious department and assistant professor of pediatrics at Western Reserve University.

Dr. Beck Lectures at Navy Medical Center.—At the second of the series of guest lectures sponsored by the Navy Medical Center, Bethesda, Md., Dr. Claude S. Beck, professor of neurosurgery at Western Reserve Medical School, Cleveland, was the guest speaker. His subject was "Revascularization of the Heart for Angina Pectoris and Coronary Artery Thrombosis." These monthly meetings are open to the local medical societies, faculties and students of medical schools and medical officers of the Army, Navy, Public Health Service and Veterans Administration in the vicinity of Washington, D. C.

PENNSYLVANIA

Blair County Adopts Emergency Call Plan.—The Blair County Medical Society has adopted an emergency call plan which provides for two alternate physicians for each doctor listed at the physicians' exchange. The plan is for emergency purposes only.

Philadelphia

Dedicate Fels Research Institute.—The Samuel S. Fels Research Institute of Temple University School of Medicine was dedicated October 22-23. A symposium on recent advances in gastric physiology was held Friday afternoon. The principal address at the dedicatory exercises was delivered by Edwin G. Conklin LL.D., Princeton, N. J., after which Mr. Samuel S. Fels spoke on the purposes of the institute, of which Dr. Harry Shay is the director.

Television in Teaching Surgery.—The University of Pennsylvania School of Medicine will install television facilities for visual education of medical students in its Philadelphia Medical Center, according to the *Chicago Daily News*. Dr. Robin C. Buerki, vice president in charge of medical affairs, said that medical students will study surgery from a video screen in the same room in which they study other subjects, permitting elimination of students' galleries in operating rooms and the saving of valuable space.

TENNESSEE

Professor Wallgren to Lecture.—Dr. Arvid J. Wallgren, Stockholm, Sweden, will arrive in the United States about March 1, 1949 to deliver the next Abraham Flexner lectures at the Vanderbilt University School of Medicine, Nashville. Dr. Wallgren has been associate professor of internal medicine at Upsala University and head of pediatrics at the Royal Caroline Medical Institute since 1942. This lectureship is awarded every two years to a scientist of outstanding attainment who shall spend as much as two months in residence in association with a department either of a fundamental science or of a clinical branch.

VIRGINIA

Appointed to State Health Department.—Dr. Albert S. McCown, Seattle, has been appointed director of the Bureau of Communicable Disease Control of the Virginia Department of Health, Richmond. Dr. McCown received his M.D. degree at Johns Hopkins University School of Medicine, Baltimore, 1918. He has served in the Washington State Health Department, the U. S. Children's Bureau in Washington, and has been director of medical and health service of the American Red Cross since 1940. During the late war he was a colonel in the medical reserve corps of the Army.

Establish Two Annual Lectures.—The executive committee and the medical staff of the Memorial Hospital, Winchester, have established two annual lectures in connection with the regular monthly staff conferences. The Frank N. Hack lecture will be given by Dr. Alfred Blalock, Baltimore, on "Surgical Treatment of Congenital Cardiovascular Defects," November 17 at the hospital. Dr. Hack of Winchester has greatly aided in the construction and maintenance of the newer portions of the hospital. The Hunter H. McGuire lecture will be given by Dr. Irving S. Wright, New York, on "The Use and Abuse of Anticoagulant Therapy in the Treatment of Thromboembolic Diseases." Dr. McGuire has been president of the hospital since its organization in 1901.

WEST VIRGINIA

Personals.—Dr. Arkie B. Bowyer, Charleston, was elected commander of the West Virginia department of the Veterans of Foreign Wars at the annual meeting in June.——Dr. Alexander Witkow, director of the bureau of county health work of the state department of health, has resigned, effective October 1, to accept a similar position at Worcester, Mass.

State Association Favors Establishment of Medical School.—The council of the West Virginia State Medical Association has gone on record as favoring the establishment at Charleston of a four year school of medicine and dentistry of West Virginia University to provide for the graduation annually of fifty doctors and twenty-five dentists. The recently released university budget carries an item of $2,000,000 for a medical school, which the council will ask to be increased by $500,000, the estimated amount needed for adding the dental school. The need for the school has been more apparent this year than ever before, according to the association. There are 436 students taking premedical work and 93 students taking predental work at the university during the fall semester. There were 181 applications for enrolment in the medical school from bona fide residents of the state for the semester beginning September 1948. Only 30 of this number could be accepted. Over 600 applications for enrolment in the medical school are on file from students residing in other states.

WISCONSIN

Lecture on Nutrition in China.—The University of Wisconsin Medical Society will present Dr. H. C. Hou, director of the Institute of Nutrition in Nanking, China, in a lecture on "Nutritional Deficiency Disease Problems in China" November 17 at 4 p. m. in the Memorial Institutes Building, Madison. Dr. Hou, a medical graduate of Pekin University, has done graduate work at McGill University and now is working in the biochemistry department of the University of Wisconsin before returning to China.

Annual Preceptors' Meeting.—The extramural teaching group of preceptors of the University of Wisconsin Medical School, Madison, hold their annual scientific meeting November 19-20. A symposium on "The Human Back and Its Disabilities" will be held in the auditorium of the Service Memorial Institutes Building on November 19. The following day's program includes ward rounds in the Wisconsin General Hospital, departmental conferences and a lecture by Dr. Clinton N. Woolsey, newly appointed Charles Sumner Slichter research professor in neurophysiology.

GENERAL

Society News.—The American Society of Maxillofacial Surgeons, at its annual meeting at Ann Arbor, Mich., September 26-29, elected Dr. Varaztad H. Kazanjian, Boston, president; Dr. Conrad I. Karleen, Minneapolis, vice president; Dr. Casper M. Epsteen, Chicago, secretary, and Dr. Maurice J. Hickey, New York, treasurer.

Survey Finances of Voluntary Hospitals.—The American Hospital Association, at its annual meeting in Atlantic City September 20, announced the formation of fifteen study groups to be known as the Commission of Hospital Finance. A two year study to determine present and future incomes of the voluntary hospitals of the nation will be made. The cost of the study is estimated at $300,000.

Pharmacopoeial Headquarters.—In conformity with instruction and authority of the 1950 Pharmacopoeial Convention, the board of trustees have selected permanent headquarters of the United States Pharmacopoeia at 46 Park Avenue, New York. The new building is within walking distance of Grand Central Station, the Pennsylvania Railroad Station and the Air Lines Terminal on 42nd Street.

Medical Director Appointed.—Dr. George F. Wilkins, Brookline, Mass., became medical director of the New England Telephone and Telegraph Company, Boston, October 1. He had been assistant medical director since 1940 and succeeds Dr. Daniel L. Lynch, retiring after thirty years as the company's first medical director. Dr. Wilkins is a graduate of Harvard Medical School, Boston, 1932, and an assistant in surgery at the Harvard Medical School.

Defective Vision in School Children.—The National Society for the Prevention of Blindness reports that one fifth of all school children have defective vision. The society made a nationwide survey in which questionnaires were submitted to school superintendents and state, county and city officials. Reports were received from twenty-five states. Dr. Franklin M. Foote is executive director of the society. Six hundred schools throughout the country are said to have sight conservation classes.

Railway Surgeons Meeting.—The American Association of Railway Surgeons will hold its national convention, commemorating the sixtieth year of its founding, at the Palmer House, Chicago, November 21-23, under the presidency of Dr. James E. M. Thomson, Lincoln, Neb. Chicago physicians will present a symposium on "Low Back Pain" November 21. There is no registration fee, and all members of the medical profession are invited. At the dinner session Monday evening, Dr. Thomson, will speak on "Recent Observations of Medicine in Central Europe."

Cerebral Palsy Fellowships.—The National Society for Crippled Children and Adults, 11 S. LaSalle St., Chicago 3, will administer a limited number of inservice fellowships for persons specializing in employment problems of victims of cerebral palsy. The fellowships have been made possible by provisions for an annual grant of $5,000 from the Alpha Gamma Delta, international women's college fraternity. Grants will cover expenses including tuition. By surveying public and private counseling and placement agencies, the national society will develop agreements for the training of workers among those agencies about to conduct intensive programs for the physically handicapped.

International Classification of Diseases.—The World Health organization at the end of this year will publish its "Manual of International Classification of Diseases, Injuries and Causes of Death." Since the World Health Organization has no facilities for distributing the manual, the Council on Vital Records and Vital Statistics has agreed to consolidate U. S. orders and distribute the volumes received from the World Health Organization. The price of the first printing of the new classification is $2.50 a set of two volumes, delivered to the purchaser. Orders must be received by December 1 with checks payable to Halbert L. Dunn, M.D., secretary-treasurer, Council on Vital Records and Vital Statistics, % National Office of Vital Statistics, Washington 25, D. C.

Life Insurance Medical Research Grants.—Applications for grants in aid of research on cardiovascular problems to begin in 1949 will be received by the Life Insurance Medical Research Fund up to Jan. 15, 1949. Support is available for physiologic, biochemical and pathologic research which bears on cardiovascular problems, as well as for clinical investigation in this field. Preference is given to fundamental research. About $500,000 will be awarded. Applications for postgraduate fellowships for training in research in 1949-1950 will be received by the fund up to Jan. 1, 1949. An M.D. or Ph.D. degree or the equivalent is required. The annual stipend is $2,500 and $3,500, with larger amounts in special cases. About twelve fellowships will be available. Later in the year the fund will also offer a number of student (predoctoral) research fellowships for 1949-1950. Both grants and fellowships will become available on July 1, 1949. Further information may be secured from the Scientific Director, Life Insurance Medical Research Fund, 2 East 103d Street, New York 29.

Fischbach Residency Foundation.—This organization has awarded residency appointments to Drs. Robert F. Hall, Flint, Mich., resident in orthopedics at the Children's Hospital, Denver; John S. Chambers Jr., Boston, resident in thoracic surgery, University Hospital, Ann Arbor, Mich.; George L. Torassa Jr., San Francisco, resident in urology, Stanford University Hospitals, San Francisco. The foundation was established early in 1947 by Dr. and Mrs. Howard P. Fischbach, of Cincinnati, through the Educational Fund of Delta Tau Delta fraternity to provide assistance to young men of special merit. The awards are outright gifts to help medical men to take advantage of residency appointments without undue hardship. Specific requirements are that residency be performed in a hospital approved by either the American Medical Association or the American College of Surgeons. The grants are made on the recommendation of a committee of three, Drs. Howard P. Fischbach and Victor W. Fischbach, of Cincinnati, and Dr. Ernest E. Irons, Chicago. The Foundation itself at present provides income sufficient for one award. Individual gifts for the current year have made possible the two additional awards.

FOREIGN

Congress of Acupuncture.—The Third International Congress of Acupuncture will be held in Paris, June 3-5, 1949, at the auditorium of the Geographical Association, 184, Boulevard St. Germain, Paris. President of the congress is Dr. R. de la Fuye, 8, avenue Franklin D. Roosevelt, Paris. The courses in Chinese medicine (acupuncture) will be held at the Room for Biotherapy, 5 rue Paul Baruel, Paris XVe, November 16 and all the following Tuesdays at 9 p. m.

Prize for Essay on Tuberculosis.—One hundred guineas will be awarded for the best essay on "The Control of Tuberculosis in a British Colony." The competition is open to doctors in the British Colonial Medical Service who are not of more than ten years' or less than five years' medical standing, of which at least three years were spent overseas. Essays should reach Dr. Harley Williams, National Association for the Prevention of Tuberculosis, London, not later than March 1, 1949.

Greeks Release Medical Hoard.—Vast quantities of vitally needed medical equipment and supplies hoarded in Greek warehouses were released last year at the insistence of the Public Health Division of the American Aid Mission, according to a *Chicago Tribune* Press Service writer, E. R. Noderer. A warehouse in Canea, Crete, released stocks that had remained untouched for four years. Most of the supplies were shipped in by UNRRA and are currently valued at $4,000,000 to $5,000,000.

The French-American Hospital.—The cornerstone for the French-American Hospital, dedicated to the United States 29th Division, was laid in St. Lo, July 18. Building funds included $140,000 raised by private subscription in America. Part of the ceremony was the unveiling of a bust of Major Thomas D. Howie of Staunton, Va., known as "the major of St. Lo," killed in action along with 1,818 men in his division in the battle of the beaches the day before St. Lo fell. One wing of the hospital will be devoted to the care of children and will be paid for out of receipts from the insurance which covered the Friendship Train's supplies destroyed in a Paris fire last February.

Chinese Medical College Moves to Foochow.—Cheeloo University College of Medicine moved from Tsinan to Foochow in August and opened the autumn semester on October 1. Preclinical work will be carried on in the old Theological School Building on Nantai, while the work of the three upper years will be done in the three mission hospitals, Union Hospital (American Methodist and American Board Missions), Christ's Hospital and Tak Ting Hospital (Church Missionary Society, England). Of these, the two former are situated in the city and the latter on Nantai. The cooperation of the staffs of these hospitals and the help and interest of the Foochow community and the Cheeloo alumni have greatly facilitated the setting up of the medical college in its new surroundings.

Deaths in Foreign Countries

Dr. Gustave Roussy, former rector of the University of Paris and dean of the faculty of sciences, noted for his work in neurology, endocrinology and cancer, died in Paris, September 30, aged 73.——**Dr. Charles M. Wenyon,** London, formerly director of the Wellcome Research Institute, which he had served in a consultant capacity since his retirement in 1944, died in London October 24 at the age of 70. The Theobald Smith Gold Medal of the American Academy of Tropical Medicine was once awarded to Dr. Wenyon.

CORRECTIONS

Hepatic Localization of Emetine.—In the Current Comment by this title in The Journal, October 23, page 596, the name of the author whose work is reviewed is Dr. Leo G. Parmer, not Palmer as printed erroneously both in the text of the Current Comment and in the footnote at the bottom of the page.

Chloromycetin.—In the editorial on chloromycetin in The Journal October 9, the following quoted statements appeared in the last paragraph: "According to the daily press even more spectacular therapeutic effects were afterward obtained during an outbreak of epidemic typhus in Bolivia. Details are not yet reported." The work referred to was begun in December 1947 by Drs. Eugene H. Payne and José A. Knaudt, who, together with Dr. Sylvio Palacios, reported their results in *The Journal of Tropical Medicine and Hygiene* of April 1948, previous to which time they reported their results before the Medical Society at La Paz, Bolivia, and before the regional meeting of the American Federation for Clinical Research. Dr. Payne writes that this was the first time this drug was used against human disease.

Dietary Lipids in Tuberculosis.—In the editorial by this title in The Journal of Oct. 2, 1948, page 366, Dubos and Davis's paper *(Journal of Experimental Medicine* **83**:409, 1946) was said to support the following conclusion: "It seemed probable therefore that dietary lipids might exert either beneficial or deleterious effect in clinical cases, depending on the type of lipid used. This conclusion was tested by Dubos and Davis of the Rockefeller Institute, who studied the growth of Mycobacterium tuberculosis in liquid mediums containing a series of fatty acids: They found that capric, lauric, palmitic and myristic acids were inhibitory at dilutions as high as 1:10,000,000. Growth occurred at concentrations as high as 1:100 with stearic, oleic, linoleic or butyric acids."

Dubos and Davis state that this conclusion not only is unsupported by their paper but is in large part directly contradictory to their findings.

Marriages

Nathaniel J. Pulver, Brooklyn, to Miss Shirley Thelma Fivel of Mechanicville, N. Y., at Troy, N. Y., recently.

Norman U. Messiter, Oneida, N. Y., to Miss Betty Cobb of Cassapolis, Mich., at Folkstown, Ga., August 14.

Marshall Henry Williams Jr., New Haven, Conn., to Miss Mary Butler of Fieldston, N. Y., August 27.

Francis Joseph Thomas Crilley Jr., to Miss Edith Louise Rupertus, both of Washington, D. C., August 14.

Joseph B. Watrous Jr., to Miss Katharine Stone Couper, both of Binghamton, N. Y., September 4.

Julius D. Stein, Milford, Conn., to Miss Francine Betty Lebenstein of New York, August 22.

Hyman M. Chernoff, New Haven, Conn., to Miss Sulamith Scharfstein of New York, August 29.

Gennady Platoff, New Rochelle, N. Y., to Miss E. Donya Pogrebniak of Binghamton, recently.

George Gregory Miles, Downsville, N. Y., to Miss Elizabeth Julia Palmer of Walton, August 14.

John R. Harrie, Grey Eagle, Minn., to Miss Jean Christy of Jamestown, N. D., September 2.

Henry H. Fetterman, Allentown, Pa., to Miss Marian Harer of Upper Darby, June 19.

Josef R. Martin to Miss Jeanne Louise McCoy, both of Carroll, Iowa, August 28.

Abraham J. Gorday, Chicago, to Miss Carmel Dunford in Eustis, Fla., August 22.

Alexander J. Kelly Jr., to Miss Mary Ann Hard, both of Brooklyn, August 14.

Eugene Smith to Miss Marvel Holck, both of Waterloo, Iowa, September 3.

Deaths

Philip Kingsnorth Gilman ⊕ San Francisco; born in 1879; Johns Hopkins University School of Medicine, Baltimore, 1905; clinical professor of surgery, emeritus, Stanford University School of Medicine; at one time on the faculty of the University of the Philippines College of Medicine in Manila, where he was on the staff of the Philippine General Hospital; member of the founders group of the American Board of Surgery; past president of the California Medical Association and the San Francisco County Medical Society; member and past president of the Pacific Coast Surgical Association; fellow of the American College of Surgeons; served during World War I; during World War II a captain in the medical corps of the U. S. Naval Reserve, serving as district medical officer of the Twelfth Naval District; chief of the bureau of hospitals, state public health department; died in Stanford University Hospital September 7, aged 69.

Edward Peter Heller ⊕ Kansas City, Mo.; born at Allentown, Pa., on Oct. 30, 1892; Jefferson Medical College of Philadelphia, 1916; member of the American Association of Industrial Physicians and Surgeons, of which he had been vice president; past president and co-founder of the Association of Railway and Industrial Physicians and Surgeons of Kansas City; formerly councilor of the Seventh District of the Missouri State Medical Association; served overseas during World War I; affiliated with Kansas City General and Research hospitals; in 1923 was awarded the Alvarenga Prize by the Philadelphia College of Physicians for his essay entitled "Treatise on Echinococcus Disease"; served as editor and co-editor of the *Jackson County Medical Society Weekly Bulletin;* died in Chadron, Neb., August 19, aged 55, of injuries received in an automobile accident.

William J. Mellinger, Santa Barbara, Calif.; born in 1886; Chicago College of Medicine and Surgery, 1913; served as associate professor of anatomy at the University of Southern California School of Medicine in Los Angeles; specialist certified by the American Board of Otolaryngology; member and formerly vice president of the American Academy of Ophthalmology and Otolaryngology; member of the American Medical Association and the American Laryngological, Rhinological and Otological Society; member and past president of the Pacific Coast Oto-Ophthalmological Society; past president of the Santa Barbara County Medical Society; affiliated with the Santa Barbara Cottage, Santa Barbara General and St. Francis hospitals; died August 28, aged 61, of coronary thrombosis.

Alfred John Murrieta ⊕ Los Angeles; born in Temecula, Calif., Nov. 30, 1876; University of Southern California College of Medicine, Los Angeles, 1899; associate clinical professor of surgery at his alma mater; formerly on the faculty of the College of Medical Evangelists; specialist certified by the American Board of Surgery; member and formerly vice president of the American Proctologic Society; fellow of the American College of Surgeons; president of the Southern California Proctologic Society; affiliated with the Los Angeles County, St. Vincent's and Cedars of Lebanon hospitals and the Hospital of the Good Samaritan; died August 6, aged 71, of cardiovascular disease, following an abdominal operation.

Vera Viola Norton ⊕ Waverly, Iowa; Northwestern University Woman's Medical School, Chicago, 1899; fellow of the American College of Chest Physicians; member of the American Trudeau Society, National Tuberculosis Association and the American Association of University Women; in 1945 the medical library at Dunham Hospital in Cincinnati was named in her honor; on the staff of the Edward Sanatorium in Naperville, Ill., from 1913 to 1917, when she joined the Hamilton County Tuberculosis Sanatorium in Cincinnati, where she retired in 1941 as associate medical director; died in St. Joseph's Mercy Hospital August 11, aged 71, of metastatic carcinoma.

Edward Leland Kellogg ⊛ New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1895; on the faculty of the New York Polyclinic Medical School and Hospital; fellow of the American College of Surgeons; member of the New York Academy of Medicine and the New York Gastro-Enterological Society; served on the staffs of Gouverneur, Manhattan General, St. Bartholomew and Broad Street hospitals; visiting surgeon at the New York Polyclinic Medical School and Hospital, where he died August 11, aged 76, of diabetes mellitus and hepatitis.

Wilfred Eugene Alton, Fort Dodge, Iowa; Chicago Homeopathic Medical College, 1896; died July 10, aged 85.

Cyril Barnert, Westbury, N. Y.; New York University College of Medicine, 1939; member of the American Medical Association; served during World War II; died July 27, aged 32.

Edward Berg, Chicago; Chicago Medical School, 1921; died in September, aged 72.

George Carlton Berkley ⊕ St. Albans, Vt.; University of Vermont College of Medicine, Burlington, 1894; formerly associated with the U. S. Public Health Service; awarded a gold fifty year service pin by the Franklin County Medical Society; died in the Mary Fletcher Hospital in Burlington, September 1, aged 78, of heart disease.

William Francis Bowen, Topeka, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1898; member of the American Medical Association, serving as a member of its House of Delegates in 1934 and 1935; past president of the Kansas Medical Society; fellow of the American College of Surgeons; formerly on the faculty of his alma mater; on the staff of the Christ Hospital; received the honorary degree of master of surgery from Washburn College in 1913; died July 25, aged 76.

Kenneth Warren Buell ⊕ Eaglebridge, N. Y.; Atlanta College of Physicians and Surgeons, 1910; Fordham University School of Medicine, New York, 1914; died August 21, aged 63.

Emmett Duane Carmalt, Pittsburgh; Hahnemann Medical College and Hospital of Philadelphia, 1926; member of the American Medical Association; affiliated with the Shadyside Hospital; died August 24, aged 54, of injuries received in an automobile accident.

William Benjamin Chamberlin, Baton Rouge, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1906; member of the American Medical Association; served in France during World War I; since Aug. 16, 1941 medical director and chief of surgical service at Louisiana State University; affiliated with Our Lady of the Lake Sanitarium and Baton Rouge General Hospital; died July 29, aged 69.

John August Christenson ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; formerly president of the board of directors of the Augustana College in Rock Island; on the staff of the Augustana Hospital; died September 13, aged 76, of bilateral pyelonephritis and uremia.

Frank Emerson Farmer, St. Johnsbury, Vt.; University of Vermont College of Medicine, Burlington, 1899; past president of the Vermont State Medical Society and the Vermont State Board of Medical Registration; member of the American Medical Association; past president of the Northeastern County Medical Society; president and director of the Citizens Savings Bank and Trust Company; died August 8, aged 74, of carcinoma of the lung.

Harry Leland Fifield ⊕ Syracuse, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1906; formerly superintendent of the Onondaga General Hospital; died August 19, aged 67, of cerebral hemorrhage, fracture of hip due to a fall and arteriosclerosis.

Rowland Houghton Ford, Washington, D. C.; Columbian University Medical Department, Washington, 1900; member of the American Medical Association; served during World War I; formerly passed assistant surgeon in the U. S. Public Health Service reserve and assistant health officer of the District of Columbia; died in the Doctors Hospital August 23, aged 73, of coronary heart disease.

Ray Samuel Friedley ⊕ Akron, Ohio; Starling-Ohio Medical College, Columbus, 1911; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; associated with the medical department of the Goodyear Tire & Rubber Company; past president of the Summit County Medical Society; served on the staffs of Children's Hospital and City Hospital, where he died August 1, aged 60, of cardiac decompensation.

Edward Louis Friedman ⊕ Forest Hills, N. Y.; Cornell University Medical College, New York, 1906; died August 9, aged 63, of coronary thrombosis.

Lee Burton Furgerson ⊕ Waterloo, Iowa; State University of Iowa College of Medicine, Iowa City, 1925; died in St. Francis Hospital August 9, aged 49, of cerebral hemorrhage and peritonitis.

Angelo Adam Gallo ⊕ Pottstown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1926; affiliated with Pottstown Hospital, where he died August 14, aged 48, of coronary occlusion.

Clifford Jackson Gay, Jacksonville, Fla.; University of Georgia School of Medicine, Augusta, 1936; member of the American Medical Association; interned at the James M. Jackson Memorial Hospital in Miami; served as a captain in the medical corps, Army of the United States, during World War II; died August 5, aged 43.

Omer Rand Gillett ⊕ Colorado Springs, Colo.; Jefferson Medical College of Philadelphia, 1902; past president of the El Paso County Medical Society; member of the American Public Health Association; city health officer; served during World War I; affiliated with the Glockner Sanatorium and Hospital, St. Francis Hospital and Sanatorium and the Memorial Hospital; died July 9, aged 73.

John Conrad Gross, Phoenicia, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1899; died August 10, aged 70, of cerebral hemorrhage.

Conrad K. Hahn, Racine, Wis.; Medizinische Fakultät der Universität Wien, Austria, 1895; member of the American Medical Association; died in St. Luke's Hospital August 19, aged 79, of arteriosclerotic heart disease.

Maurice Edmund Harwood, Pittsburgh; University of Pittsburgh School of Medicine, 1936; member of the American Medical Association; died July 16, aged 44.

Albert H. Haworth, Troy, Ohio; Starling Medical College, Columbus, 1895; member of the American Medical Association; died July 30, aged 78, of heart disease.

Maurice Edward Healy, Niagara Falls, N. Y.; Loyola University School of Medicine, Chicago, 1937; died July 17, aged 38, of cardiovascular disease and cerebral hemorrhage.

Horace L. Heistand, Springfield, Ohio; Medical College of Ohio, Cincinnati, 1891; member of the American Medical Association; died July 6, aged 82, of uremia and arteriosclerosis.

William Walter Massey Henry, Dover, Del.; Howard University College of Medicine, Washington, D. C., 1909; affiliated with Kent General Hospital; died July 19, aged 66, of carcinoma of the colon.

Horace Bruce Hetrick, Wellsville, Pa.; University of Maryland School of Medicine, Baltimore, 1888; died August 11, aged 81, of arteriosclerosis.

Beeler David Higbee, Grosse Pointe, Mich.; University of Louisville (Ky.) Medical Department, 1908; died August 3, aged 65, of tumor of the lung.

George Jacob Hinn, Highland Park, Ill.; Illinois Medical College, Chicago, 1904; member of the American Medical Association; died in St. Francis Hospital, Evanston, Ill., August 8, aged 75, of coronary thrombosis.

Matthew J. Hoenig, Rochester, N. Y.; University of Buffalo School of Medicine, 1919; member of the American Medical Association; fellow of the International College of Surgeons; on the staffs of St. Mary's and Highland hospitals; died August 5, aged 55, of cerebral hemorrhage.

Archie Solomon Horn ⊕ Rib Lake, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the New Mexico Medical Society; served as health officer of Rib Lake; a captain in the medical corps of the U. S. Army during World War I; died August 22, aged 67, of cerebral vascular accident.

Irwin Wilson Howard ⊕ Aurora, Ill.; Ohio Medical University, Columbus, 1904; died in the Copley Memorial Hospital August 2, aged 69, of arteriosclerotic heart disease.

Charles David Huber, Charlotte, Mich.; Detroit College of Medicine, 1901; member of the American Medical Association; past president of the Eaton County Medical Society; affiliated with the Hayes-Green-Beach County Memorial Hospital; died September 1, aged 71, of heart disease.

Irving Emerson Hunt ⊕ Clarksville, Tenn.; University of Nashville Medical Department, 1907; died July 27, aged 67, of carcinoma of the stomach.

William Butler Hunt, Terre Haute, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1901; member of the American Medical Association; formerly county health officer; died July 31, aged 87, of heart disease.

Orton Charles Hyslop, Spring Valley, Ill.; Northwestern University Medical School, Chicago, 1916; served during World War I; died in People's Hospital, Peru, July 28, aged 56, of coronary thrombosis and hypoadrenalism.

George Hills Iler, Brooklyn; New York Homeopathic Medical College and Hospital, New York, 1890; fellow of the American College of Surgeons; for many years affiliated with Cumberland Hospital; visiting surgeon to the Carson C. Peck Memorial Hospital; died August 11, aged 80, of carcinoma of the bladder.

Matthew William James, Bensenville, Ill.; Reliance Medical College, Chicago, 1911; village health officer; affiliated with the Memorial Hospital, Elmhurst, and the Walther Memorial Hospital in Chicago, where he died August 25, aged 66, of general peritonitis following an operation.

James Morton Jenkins, Cortland, Ind.; Kentucky School of Medicine, Louisville, 1891; member of the American Medical Association; died at Norways Sanatorium, Indianapolis, July 9, aged 83, of coronary thrombosis.

Allen Jones Jervey ⊕ Tryon, N. C.; Medical College of the State of South Carolina, Charleston, 1905; past president of the Polk County Medical Society; served during World War I; affiliated with St. Luke's Hospital, where he died August 25, aged 67, of uremia.

Wilbur Vogt Johnson, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; member of the American College of Chest Physicians; served on the staff of the City of Chicago Municipal Tuberculosis Sanitarium; died in the Belmont Hospital August 29, aged 70, of carcinoma of the stomach.

Jerry M. Jones ⊕ Bay City, Mich.; Michigan College of Medicine and Surgery, Detroit, 1896; chief surgeon for the Detroit Mackinaw Railway; for many years operated the Jones Clinic; medical director of the Bay City Samaritan Hospital; died August 9, aged 77, of heart disease.

Oliver P. Judkins, Indianola, Iowa; College of Physicians and Surgeons, Keokuk, 1895; Rush Medical College, Chicago, 1898; an examiner of the county draft board during World War I; died in Methodist Hospital, Des Moines, August 9, aged 77, of hypertensive cardiovascular disease.

Aquin Sarsfield Kelly ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1900; past president of the New York Ophthalmological Society; specialist certified by the American Board of Ophthalmology; affiliated with Meadowbrook Hospital, Hempstead, St. Joseph Hospital, Far Rockaway, New York Eye and Ear Infirmary and St. Vincent's Hospital; died in the Nassau Hospital, Mineola, July 20, aged 71, of carcinoma of the lung.

John Martin Kinnunen, Meadville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1931; interned at the Mercy Hospital in Pittsburgh; member of the American Medical Association; served in the medical corps, Army of the United States, during World War II; medical inspector for the school district, served as county medical director; affiliated with Meadville City Hospital and Spencer Hospital, where he died July 9, aged 43, of myocarditis.

Wilmer Carroll Kipe, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1905; died recently, aged 69, of coronary heart disease and diabetes mellitus.

Samuel M. Klaristenfeld ⊕ New York; New York Medical College and Flower Hospital, New York, 1930; served during World War II; affiliated with Flower and Metropolitan hospitals; died July 11, aged 43, of pemphigus and heart disease.

Willard Daniel Kline ⊕ Allentown, Pa.; Jefferson Medical College of Philadelphia, 1901; fellow of the American College of Physicians; past president of the Lehigh County Medical Society; for many years affiliated with the Sacred Heart Hospital; died August 9, aged 71, of carcinoma of the larynx, diabetes mellitus and hypertensive cardiovascular disease.

Heilner Maxwell Langdon ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1901; specialist certified by the American Board of Ophthalmology; served as professor of ophthalmology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; member of the American Ophthalmological Society; affiliated with the University, Children's and Presbyterian hospitals; died in Hampton, N. H., August 28, aged 72, of angina pectoris.

Dwight Milton Lewis ⊕ New Haven, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1901; member of the American Public Health Association; served during World War I; at one time director of rural health in the West Virginia State Department of Health; formerly epidemiologist for the city department of health; died in the New Haven Unit, Grace-New Haven Community Hospital, August 31, aged 73, of coronary occlusion.

James Marshall Lilly, Fayetteville, N. C.; University College of Medicine, Richmond, 1903; member of the American Medical Association; fellow of the American College of Surgeons; served as president of the North Carolina Eye, Ear, Nose and Throat Society; on the staff of the Highsmith Hospital, where he died August 1, aged 70, of sarcoma of the lung.

Richard Mitchell Little ⊕ Surgeon, Lieutenant Commander, U. S. Navy, retired, Dallas, Texas; Columbian University Medical Department, Washington, D. C., 1902; entered the U. S. Navy on Dec. 21, 1920; retired Oct. 1, 1941; died September 3, aged 69, of coronary occlusion.

Finis London, Woodburn, Ky.; University of Tennessee Medical Department, Nashville, 1900; Hospital College of Medicine, Louisville, 1901; member of the American Medical Association; died July 23, aged 74, of hypertension and heart disease

Henry Edmund Lynch, Holyoke, Mass.; Tufts College Medical School, Boston, 1911; served during World War I; on the staff of Providence Hospital; died August 9, aged 61, of coronary thrombosis.

Carroll Edward McCarthy, Clinton, Tenn.; University of Tennessee College of Medicine, Memphis, 1940; member of the American Medical Association; served during World War II; died in St. Mary's Hospital, Knoxville, August 20, aged 29, of heart disease.

Alexander Hancock McChrystal, Salt Lake City; University of Pennsylvania Department of Medicine, Philadelphia, 1901; died August 28, aged 72.

Neil James McColl, Port Huron, Mich.; Medical College of Indiana, Indianapolis, 1898; member of the American Medical Association; formerly mayor of Whittemore and of Croswell; died July 25, aged 71, of cerebral hemorrhage.

Grant McDonald, Detroit; Detroit College of Medicine, 1900; member of the American Medical Association; affiliated with the Florence Crittenton and Children's hospitals; died in the Harper Hospital August 23, aged 78, of carcinoma of the bladder.

James Mahlon McElroy, Alabama City, Ala.; University of the South Medical Department, Sewanee, Tenn., 1901; member of the American Medical Association; died July 21, aged 73.

Harvey Benton McGarrah ⊕ Fairbank, Pa.; Baltimore Medical College, 1893; died in the Uniontown (Pa.) Hospital August 24, aged 82, of arteriosclerosis.

Eben Seton McIntosh ⊕ Burns, Kan.; University of Wooster Medical Department, Cleveland, 1894; died in Newton August 7, aged 81, of bronchopneumonia.

Daniel B. Mark ⊕ Minneapolis; Barnes Medical College, St. Louis, 1909; on the staffs of the Asbury and Eitel hospitals; died in Northwestern Hospital July 4, aged 61, of acute coronary thrombosis.

Charles Wesley Mattison, Temple City, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; member of the American Medical Association; served on the staff of the French Hospital in Los Angeles; died August 26, aged 74, of Parkinson's disease and bronchopneumonia.

Louis Henry Mayer Jr. ⊕ Johnstown, Pa.; Jefferson Medical College of Philadelphia, 1913; past president of the Cambria County Medical Society; served during World War I; consultant on the staffs of the Pennsylvania State Tuberculosis Sanatorium in Cresson and the Municipal Hospital; affiliated with Mercy Hospital and Conemaugh Valley Memorial Hospital, where he died July 10, aged 58.

John Earle Meloy ⊕ Peoria, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; affiliated with Methodist Hospital; died in Grand Rapids, Minn., August 4, aged 77, of arteriosclerosis.

Edgar Benjamin Merwin, Manlius, N. Y.; University of the City of New York Medical Department, New York, 1891; member of the American Medical Association; served as village health officer and school physician; died July 7, aged 82, of coronary thrombosis.

Roy Heape Milligan ⊕ St. Louis; St. Louis University School of Medicine, 1915; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; assistant professor of clinical otolaryngology at his alma mater; affiliated with St. Mary's Group of Hospitals; died in August, aged 58, of heart disease.

Charles Willard Mims, Greenville, S. C.; Medical College of the State of South Carolina, Charleston, 1943; member of the American Medical Association; interned at Greenville General Hospital; died July 24, aged 30.

Walter N. Miner, Calais, Me.; Baltimore Medical College, 1898; member of the American Medical Association; fellow of the American College of Surgeons; served as mayor, alderman, state senator and representative; for many years president of the chamber of commerce; died July 15, aged 76, of angina pectoris.

John Henry Moore, Delaware, Ark. (licensed in Arkansas in 1903); member of the American Medical Association; died July 16, aged 78, of arteriosclerosis and coronary heart disease.

John Henry Moore, Fort Smith, Ark.; Meharry Medical College, Nashville, Tenn., 1898; died July 24, aged 84, of senility.

James W. Morrow, Portland, Ore.; Kansas City (Mo.) Medical College, 1892; died July 4, aged 91, of senility.

Bernard Joseph Mulcahy, Poughkeepsie, N. Y.; University of Vermont College of Medicine, Burlington, 1937; certified by the National Board of Medical Examiners; member of the American Medical Association; served as a flight surgeon overseas during World War II; served a residency at Brooklyn Eye and Ear Hospital; interned at the Vassar Brothers Hospital, where he was a clinical assistant; affiliated with St. Francis Hospital; died August 21, aged 36, of coronary thrombosis.

Raymond William Mullen ⊕ Sioux Falls, S. D.; John A. Creighton Medical College, Omaha, 1902; fellow of the American College of Surgeons; served during World War I; died recently, aged 69, of cerebral hemorrhage.

Eugene Bernhard Munier, Martin, Ky.; National University of Arts and Sciences Medical Department, St. Louis, 1915; served during World War I; died July 21, aged 67, of coronary occlusion.

Zollie Thompson Norman, Philadelphia; University of Texas Medical Branch, Galveston, 1947; interned at the Philadelphia General Hospital; died in Hempstead, Texas, July 5, aged 23, of Hodgkin's disease.

Roy Bartlett Nutter, Tegucigalpa, Honduras, Central America; Tufts College Medical School, Boston, 1908; died August 8, aged 63, of cerebral hemorrhage.

Philip Daniel O'Connor ⊕ Chicago; Loyola University School of Medicine, Chicago, 1925; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology; affiliated with the Wesley Memorial Hospital, where he died September 5, aged 51, of portal cirrhosis of the liver and bronchopneumonia.

Thomas Francis O'Loughlin, Rockville, Conn.; New York University Medical College, New York, 1896; member of the American Medical Association; served as health officer for the town of Vernon and medical examiner for the towns of Ellington, Vernon and Tolland; for many years member of the board of education; on the staff of Rockville City Hospital; died August 8, aged 76, of lethargic encephalitis.

Richard Henry Simmons, Shamokin, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; an officer during World War I; for many years county medical director; died July 31, aged 79, of myocarditis and hypertension.

Morgan Smith, Jennings, La.; Vanderbilt University School of Medicine, Nashville, Tenn., 1906; member of the American Medical Association; president of the Jefferson Davis Parish Medical Society; for many years county coroner; died July 11, aged 65, of coronary thrombosis.

Harvey B. Speer ⊕ Coraopolis, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1903; past president and chief of medical staff of the Sewickley Valley Hospital, Sewickley; died July 30, aged 74, of carcinomatosis.

Eugene Charles Stern ⊕ Cleveland; Georg August-Universität Medizinische Fakultät, Göttingen, Prussia, Germany, 1919; member of the American Academy of Dermatology and Syphilology; on the staff of the Huron Road Hospital, East Cleveland; died July 12, aged 54, of coronary occlusion.

Clifford John Stricker ⊕ Marseilles, Ill.; Northwestern University Medical School, Chicago, 1928; died in Queen of Angels Hospital, Los Angeles, July 24, aged 50, of lymphoblastoma of the mediastinum.

John Clifton Taylor ⊕ New London, Conn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; served on staff of Lawrence Memorial Hospital, where he died July 14, aged 79, of arteriosclerotic heart disease.

Henry Muir Thelen, Vacaville, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1941; interned at the San Francisco Hospital; member of the American Medical Association; died in the Herrick Memorial Hospital, Berkeley, July 27, aged 31, of aortic stenosis and rheumatic heart disease.

Harold A. Thompson ⊕ San Diego; University of Southern California College of Medicine, Los Angeles, 1906; member of the American Society of Clinical Pathologists; affiliated with Mercy Hospital, where he died, July 31, aged 64, of arteriosclerotic heart disease, hypertension and diabetes mellitus.

Albert Leopold Wahl, Oneonta, N. Y.; McGill University Faculty of Medicine, Montreal, Canada, 1935; member of the American Medical Association; served overseas during World War II; died in Mount Vision, July 1, aged 41.

Marion McDowell Webster, Ada, Okla.; St. Louis College of Physicians and Surgeons, 1905; served overseas during World War I; died July 6, aged 72, of coronary occlusion.

The Waste of Time and Material Under Medical Socialism

The waste of the doctor's time under medical socialism has been described in previous letters. With the onset of colder weather, doctors now complain they are so flooded with patients under the National Health Service that they have not time for the examination of serious cases. Hypochondriacs and persons who have only such ailments as slight colds, for which they would not trouble a doctor if they had to pay, come in numbers. At the first annual meeting of the Executive Councils' Association of the National Health Service the Minister of Health, Mr. Bevan, confirmed this waste and referred to other forms of waste as follows: "Because things are free is no reason why people should abuse their opportunities. This is a very great test of the maturity of the British people, in so far as they have all the resources of the medical profession at their disposal without charge. The general practitioner has a very great responsibility. Over-prescribing can be as bad as under-prescribing. Some general practitioners are very conscious of the impressiveness of long lists of drugs in their prescriptions on the psychology of their patients. We want the general practitioner to prescribe what he believes is necessary, and put nothing in his way. But we want to impress on him that it is not a good thing to evoke merely a psychologic response by prescribing too expensive drugs."

Mr. Bevan said that so far the services had operated reasonably smoothly and had been enthusiastically received by the vast mass of the population. Some things—not many—had gone wrong. Large numbers were making use of the free services. It seemed that an extraordinary proportion of the population had bad sight. The rush for spectacles had been so great that it had overtaken productive capacity. He was gratified that 18,165 of the general practitioners in the country had joined the service and that 92 per cent of the population were now on doctors' lists. The total was increasing daily, and he expected that by the end of the year practically all would be participating in the scheme. The number of dentists taking part had grown to over 80 per cent. By September 17 1,000,000 persons had sought dental treatment. The number of prescriptions dispensed was phenomenal, and the rate was twice that under the previous National Health Insurance scheme. If the rate were maintained it would mean that 140,000,000 to 150,000,000 prescriptions would be dispensed annually. Addressing the Institute of Arbitrators, Lord Horder drew a very different picture of the National Health Service. He deplored the lowering of the standards of the medical profession which had resulted from the passing of the Health Act. When doctors signed on the dotted line they capitulated not from conviction but from economic necessity. The implementation of the Act was being proved entirely premature. The health benefits were not available; health centers not only did not exist but would not exist for a considerable time. The Act had been a severe blow to the standard of medical practice in this country. It would be rather grotesque if medicine had to go back to the middle ages and form a guild of doctors to see that the standard of medical treatment was kept at a level to which the community was entitled.

Vitrellae

A new word has been added to the terminology of pharmacy. The Joint Formulary Committee of the British Medical Association and the Pharmaceutical Society, which is engaged in compiling a National Formulary, has been seeking a term for those therapeutic agents which are inhaled from a crushed glass capsule. In order to distinguish them from the "vapores" (inhalations), which form a distinctive group, the word "vitrellae" (crushable glass capsules) has been chosen. This title will be used in the National Formulary for medicaments enclosed in glass capsules covered with protective fabric and intended to be inhaled after crushing the capsule; e. g., Vitrella Amylis Nitritis.

Cars for the Disabled

Among the new means for the rehabilitation of the disabled are Ford-Anglia 8 horse power cars specially adapted to the needs of exservice men and ordered by the Ministry of Pensions. The front seats can be slid right back to allow easy entry and exit for drivers with artificial limbs. Many of them have special clutch, accelerator and brake controls beneath the steering wheel.

National Interest in Gerontology

A chair on geriatrics was established at the Valencia University, in 1946, with Dr. M. Beltrán Baguena as its head. The Sociedad Española de Gerontología was recently established; it was created on motion of the Superior Council of Scientific Research. Dr. Beltrán Baguena, a professor of medical pathology, and his collaborators have carried on studies on the subject since 1936. His book, "Lecciones de Geriatría," contains lectures on the subject as they were taught by the author at the Valencia University, where geriatrics is now an obligatory subject of study. The inaugural meeting of the new society was held in Madrid, with Drs. Korenchewsky of London and Marañón of Spain as special guests. In the course of the meeting the official topics to be discussed in the First National Meeting of the Society of Gerontology of Spain were assigned. The national meeting will be held at Madrid this winter. The official speakers will be Dr. Pañella Casas, "Senile Changes of the Spine"; Dr. Navarro Gutiérrez, "Senile Tuberculosis," and Dr. Grande Cobián, "Metabolism of Carbohydrates in Senility." By a motion of Dr. Beltrán Baguena, it was resolved that the general activities of the society should mainly cover the fields of senile clinical pathology, biologic researches, demographic studies and studies for protection of the aged.

National interest in gerontology during the last few years is evident. There are important centers in various hospitals. The following are the most important: geriatric department at the Hospital Municipal de Nuestra Señora de la Esperanza in Barcelona, a very good hospital, with an excellent staff, beautiful buildings and complete up-to-date equipment. Drs. Vandrell and Martínez González are the director of the hospital and the head of the department of cardiology, respectively. Dr. Beltrán Baguena is the head of the hospital geriatric department. It was in this department that Dr. Pañella Casas organized a postgraduate course of lectures on geriatrics this year. These lectures will be published in a volume in the near future.

Dr. G. Marañón of the Instituto de Patología Médica of the General Hospital of Madrid recently established a department of geriatrics in the institute. Dr. F. Vega Díaz is the head of the department. Researches to be carried on in the department will mainly cover geriatric fields concerning endocrine and cardiologic subjects. This department will be open in October. There will be an inaugural Geriatric Week in which well known geriatric physicians of Spain and of some foreign countries will participate. During the following term of universitarian courses there will be a weekly lecture on geriatric topics. In the regular course of endocrinology in the chair of Dr. G. Marañón there will be regular lessons on endocrine geriatrics.

The National Department of Public Health recently created a permanent division which is dedicated only to sociologic research in the field of gerontology. The Sociedad Española de Gerontología will organize regular periodic geriatric lectures which will be delivered by foreign geriatric physicians who will be invited for this purpose. These lectures will begin in the near future. The studies on geriatrics in Spain are to be published in a supplemental issue of *Medicina Española,* which is edited in Valencia.

PALESTINE

JERUSALEM, Sept. 22, 1948.

Infectious Hepatitis in Pregnancy

B. Zondek and Y. M. Bromberg of Jerusalem made a study of infectious hepatitis in pregnancy during an epidemic of this disease which occurred in Palestine in the course of World War II.

Surprisingly few data have been reported during recent years when this disease complicated pregnancy. There is a tendency among obstetricians to consider infectious hepatitis in its sporadic form (hitherto known as catarrhal jaundice) as an essentially benign disease never leading to serious complications. Jaundice complicating pregnancy which leads rapidly to acute necrosis of the liver is generally considered as a particularly severe form of toxemia of pregnancy. In such cases the infective cause seems often to be overlooked, leading to misinterpretations in the diagnosis and prognosis. The clinical data reported in this study point out the fact that the benign icterus catarrhalis and the extremely serious form of hepatitis with acute liver atrophy in pregnancy should be considered as the same disease, both caused by the icterogenic virus of infectious hepatitis.

Twenty-nine patients suffering from infectious hepatitis were observed among 3,382 pregnant women over a period of thirty-two months. Of particular interest is the fact that nonpregnant women affected by hepatitis and considered as sources of contamination in many of the cases described had a mild form of hepatitis; on the other hand, some pregnant women who contracted the disease from them died of acute necrosis of the liver after a particularly severe clinical course.

It has been shown that infectious hepatitis may assume in pregnant women three different clinical courses: (1) hepatitis without jaundice (2 patients), with no clinically apparent jaundice, transitory bilirubinurea and only slight impairment of hepatic function; (2) moderately severe hepatitis (18 cases) which differs from the usual form of the disease by insidious onset with the symptoms of the preicteric stage often misinterpreted as due to pregnancy, rare occurrence of itching and bradycardia and serious functional impairment of the liver; (3) severe hepatitis with a tendency to acute necrosis of the liver (9 cases). Five of the 9 patients died from acute atrophy of the liver. The severity of the disease is indicated by pronounced mental instability, tachycardia, excessive vomiting, subsistence of pain in the liver area and reduction of the liver size; the laboratory examinations show progressive decrease of the urea blood levels, rapidly decreasing total cholesterol and cholesterol ester blood values, hypoglycemia and inadequate estrone inactivation.

In the study of factors contributing to the severity of infectious hepatitis in pregnant women, pregnancy must be considered a decisive factor aggravating the course of the disease. Moreover, undernutrition due to insufficient dietary intake or to excessive vomiting seems to play a particularly important role as an additional aggravating factor. In none of these cases studied was the fetus in utero contaminated by the disease of the mother; the virus of infectious hepatitis does not seem to be able to infect the fetus because either it does not pass the chorionic barrier or it circulates in insufficient amount in the blood to induce infection.

The treatment in cases of severe disease consisted in intravenous administration of essential nutritional factors (carbohydrates, proteins, essential amino acids and vitamins) in high doses. Blood transfusions were frequently administered. Despite treatment, 5 patients died from acute atrophy of the liver. It should be emphasized that although this mortality rate is high, 4 patients presenting symptoms of extremely grave prognostic omen (such as comatose condition, fetor hepaticus, reduction of liver size and laboratory findings of severe liver damage) could be saved.

The outstanding problem in the obstetric treatment of infectious hepatitis in pregnancy is whether artificial interruption of pregnancy should be performed. The results of this study seem to demonstrate that an active attitude is not advisable. The artificial termination of pregnancy made at the onset of the disease might sacrifice the fetus in a case in which the disease may have had a benign clinical course and greatly aggravate the hepatitis by the trauma which it involved. Cases in which there is aggravation of the clinical course after spontaneous abortion or delivery demonstrate that artificial interruption of pregnancy should be discouraged in infectious hepatitis in the interest of both mother and fetus.

Keratitis Rosacea Due to Allergy to Endogeneous Hormones

Allergy is considered to be the cause of a variety of ocular diseases. In general the disturbance is ascribed to hypersensitivity of the ocular tissue to exogeneous proteins.

B. Zondek and Y. M. Bromberg have found that patients suffering from typical allergic symptoms (asthma, vasomotor rhinitis, urticaria, angioneurotic edema) and certain other disorders not usually classified as such (premenstrual tension, pruritus vulvae, migraine) show in a certain percentage of cases hypersensitivity to their own hormones. They called this special kind of hypersensitivity "endocrine allergy."

Recently Zondek, J. Landau and Bromberg suggested that certain eye diseases of still unknown causation may be due to allergy to endogeneous hormones. The lack of any definite knowledge as to the cause of keratitis rosacea led them to test 6 patients suffering from this disease for presence of hormonal allergy. Three men and 3 women with keratitis rosacea associated with rosacea faciei of long duration (four to twenty years) which had proved refractory to the usual methods of treatment were tested by deep intracutaneous injections with various steroid hormones (estrone, estradiol, progesterone, pregnandiol, testosterone, androsterone and corticosterone). The reaction to a steroid hormone was considered positive when, twenty-four to forty-eight hours after injection of 0.1 mg. of steroid hormone dissolved in 0.1 cc. of specially purified olive oil, a red or pink slightly elevated and frequently itching papule occurred at the site of the injection.

The 6 patients with keratitis rosacea were tested with all the aforementioned hormones, with the following results: In all of them hypersensitivity to testosterone only was found. It is remarkable that in all the 6 patients examined (3 men and 3 women) the responsible hormonal allergen was always testosterone. This hormone is produced not only by Leydig's cells of the testes but also by adrenal tissue, and this circumstance probably explains the occurrence of allergy to this substance in mature women.

These descriptions pointing to the etiology of keratitis rosacea as an allergic reaction to the endogeneous testosterone do not exclude the possibility that other endogeneous hormones may act as allergens in some cases and that other causative factors may also be involved. Treatment of hypersensitivity to endogeneous hormones consists of specific desensitization by daily subcutaneous injections of the offending specific hormonal allergen in small and gradually increasing doses and in the present cases with testosterone. The initial dose of testosterone employed in desensitization should be very small, never exceeding 0.1 mg, and the increase should be gradual; administration of large doses may cause severe exacerbation.

Although therapeutic results in keratitis rosacea must be interpreted with great caution, spontaneous remissions occurring frequently, the results obtained seem to point out that the treatment was specific. The results achieved were as follows: The subjective symptoms such as photophobia, lacrimation and sensation of burning in the eyes, receded promptly and completely; the limbal and corneal vascular dilatation disappeared or considerably improved while the facial rosacea also decidedly improved. Mild recurrences in some instances promptly improved after administration of a second course of testosterone therapy. An effect on the permanent degenerative corneal changes could, of course, not be expected.

Correspondence

NEW PROBLEMS FROM NEW DISCOVERIES

To the Editor:—The excerpt from Sir Lionel Whitby on page 125 of The Journal for September 11, dealing with the new problems that immediately arise following such scientific discoveries as penicillin, streptomycin and the sulfonamide drugs, is excellent.

An appropriate postscript might be the following well known quotation from Walt Whitman:

"Now understand me well—It is provided in the essence of things, that from any fruition of success, no matter what, shall come forth something to make a greater struggle necessary."

John E. Walker, M.D., Columbus, Ga.

PHYSICIANS FOR VETERANS ADMINISTRATION

To the Editor:—We are taking the liberty of requesting your assistance in the recruitment of physicians for assignment to Veterans Administration installations in this area of Illinois, Indiana and Wisconsin. At present there is a critical need for physicians in tuberculosis, neuropsychiatry and general medicine.

It is our aim to furnish hospitalized veterans with medical care of the highest caliber. It is our desire that preference be given to the best qualified applicants and that among equally qualified persons, preference be given to veterans.

Salaries of these positions range from $4,479.60 to $10,000 per annum. Specialists certified by American specialty boards are paid an additional allowance of 25 per cent of their base salary. The grades and salaries for which applicants are eligible are determined by a Professional Standards Board, based on the individual applicant's professional background and experience. The age limit for physicians for appointment to positions in the operating service of the Department of Medicine and Surgery is 55.

Advantages of employment with the Veterans Administration are many. Physicians work with, and under the supervision of, some of the best medical men in the country. Consultants in most specialties, or full time physicians with board certification in these specialties, are assigned to our installations; this enables young physicians who have completed residencies to obtain the necessary training leading to board certification. Other advantages are opportunities for advancement, training in the newest medical technic, a liberal retirement plan, and annual or vacation leave of thirty days. Quarters are available at a number of our field installations at a reasonable rate.

The location of Veterans Administration installations, types and bed capacity, are as follows:

Veterans Administration Hospitals	Type	Bed Capacity	Teaching
Danville, Ill.	NP*	2,025	Nonteaching
Downey, Ill.	NP-TB†	2,047	Teaching
Hines, Ill.	GM&S‡	3,253	Teaching
Marion, Ill.	GM&S	176	Nonteaching
Dwight, Ill.	GM&S	256	Nonteaching
Fort Benjamin Harrison, Ind.	GM&S	500	Teaching
Indianapolis	GM&S	340	Teaching
Marion, Ind.	NP	1,924	Teaching
Tomah, Wis.	NP	1,172	Teaching
Waukesha, Wis.	TB	256	Nonteaching
Wood, Wis. (Center)	GM&S	1,463	Teaching

* Neuropsychiatric.
† Tuberculosis.
‡ General medical and surgical.

Any assistance that you can give us in obtaining services of qualified physicians for our medical staffs will be sincerely appreciated. Interested physicians may be referred to this office for additional information and the necessary application blanks or, if they so desire, they may apply directly to the installation where they desire placement.

John L. Johnston,
Director, Personnel Service,
17 N. Dearborn St., Chicago 2, Ill.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I & II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April, 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa. *Part III.* Boston & New York, Nov. 9-11, Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

American Board of Internal Medicine: *Oral.* San Francisco, Feb. 8-10, 1949. Final date for filing application is Dec. 1, 1948. New York City, March 23-25. Final date for filing application is Jan. 2. Philadelphia, June 1-3. Final date for filing application is Jan. 2. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

Tennessee: *Examination.* Memphis, Dec. 30-31. Sec., Dr. O. W. Hyman, 874 Union Avenue, Memphis 3.

Washington: Seattle, Jan. Sec., Dept. of Licenses, Miss Virginia Wotherspoon, Olympia.

Wisconsin: *Examination.* Milwaukee, Dec. 4. Final date for filing application is Nov. 27. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Right of Workmen's Compensation Commission to Subpoena Hospital Records.—During the course of a proceeding for an award under the workmen's compensation act, the Maryland Casualty Company petitioned for an order directing the Bellevue Hospital to produce certain hospital records before the Workmen's Compensation Board. From a decision ordering the director of the Bellevue Hospital to produce the hospital records in question, an appeal was taken to the supreme court, appellate division, first department, New York.

Section 119 of the workmen's compensation law provides that "a subpoena or a subpoena duces tecum may be signed and issued by the chairman, a member of the board, referee or such other officer as may be designated by the chairman. . . . Failure to obey such subpoena shall constitute a contempt as provided by the Civil Practice Act." On appeal of this case it was contended that, notwithstanding this section, the workmen's compensation board was without power to issue a subpoena duces tecum directing the production before it of hospital records at a hearing on a claim for compensation filed by the patient-employee. Four grounds were urged in support of this contention.

It was first contended that it is contrary to public policy to order records relating to mental condition to be produced at a hearing on a claim for workmen's compensation. No consideration of public policy, said the court, prevents the proper use by an injured employee of relevant hospital records relating to his mental condition. On the contrary, it would seem to be against public policy to exclude any competent and relevant evidence bearing on the nature and extent of the injuries claimed by the employee and their relation to an accident arising out of and in the course of his employment.

It was next contended that Section 34, Subdivision 9, of the mental hygiene law applied to Bellevue Hospital. This section provides that, on admission of a patient to any state institution in the Department of Mental Hygiene, a record of the case shall be kept by the director of the institution, which "record shall be accessible only to the director and such officers and subordinates of the institution as he may designate and to the commissioner and his representatives, except on the consent of the commissioner or an order of a judge of a court of record." Bellevue Hospital, said the court, is not a state institution, and its records, even if they relate to the mental condition of a patient, do not come within the purview of this section of the mental hygiene law.

The third contention was that Rule 162 of the Rules of Civil Practice requires that hospital records may be ordered produced only on order of a justice of the supreme court on one day's notice to the parties in interest. Clearly, said the court, this provision has no application to a hearing before the workmen's compensation board or a referee thereof on a claim for compensation filed by an injured employee. The rule relates only to an action or a proceeding before a court or a referee thereof. In view of the informal character of the proceedings under the workmen's compensation law, this rule should not be stretched by implication.

Finally, it was contended that under sections 352 and 354 of the civil practice act, the hospital records are privileged. We assume, said the court, that the workmen's compensation board has no right to disregard the statutory physician-patient privilege provided by the civil practice act. The physician-patient privilege, assuming it to apply, is waived, however, when a claim for compensation is not alone filed but is prosecuted by one competent to do so, since the valid prosecution of such a claim necessarily involves the giving of testimony on behalf of the claimant, with respect to the injuries alleged to have been caused by the accident. The privilege is deemed to have been waived as soon as evidence in his behalf is given of the claimant's injuries.

The order requiring the production of such records was reversed, however, because of a procedural question.—*Petition of Maryland Casualty Co., 80 N. Y. S. (2d) 181 (N. Y., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

[illegible] in Patent Ductus Arteriosus.—[illegible] used a direct ink recording microplethysmograph in a study of patients with congenital heart disease. They obtained plethysmograms in 26 patients suspected of having patent ductus arteriosus and in 6 patients with suspected coarctation of the aorta. Tracings of the finger and toe tip volume pulsations were recorded and characteristic patterns were found. In patent ductus the following alterations were found: The apex of each wave was blunt, broad or flat; there was a loss of the normal difference between systolic rise and diastolic fall, the limbs tending to be equal; the dicrotic notch was either absent or barely discernible and tended to vary in position from beat to beat; small but significant fluctuations in contour and volume amplitude appeared from moment to moment. In coarctation of the aorta normal volume relationships in the finger and toe tracings were lost, so that the volume amplitude and alpha waves in the fingertip tracing were greater than or at least equal to the analogous waves in the tracings from the toe tip. The findings illustrate the value of microplethysmography in diagnosis of these anomalies.

New Test for Pheochromocytoma.—Guarneri and Evans report preoperative diagnosis of a chromaffinoma of the adrenal gland by means of a new diagnostic test and successful removal of the tumor. The effects of methacholine chloride, atropine and curare were studied in the patient, a woman aged 23. Methacoline produced an initial transitory fall in blood pressure followed by a rise to hypersensitive levels. Atropine abolished the "muscarinic" reactions to methacholine but failed to influence the rise in pressure. Curare did not affect the response to methacholine in any way. A test for pheochromocytoma, based on the reaction to 25 mg. of methacholin given subcutaneously, is described. An initial fall in blood pressure of short duration which is followed by a decided and more sustained rise to hypertensive levels constitutes a positive reaction. Of 27 control patients receiving methacholine, none showed this hyper-reactor response. Comparison is made between the histamine and the methacholine test. In 9 patients, 5 showed a hyper-reactor response to histamine. It is suggested that the methacholine test may be more reliable than the histamine test in diagnosis of pheochromocytoma inasmuch as no hyper-reactors were noted among the controls when methacholine was administered. From the pharmacologic evidence presented it is deduced that methacholine directly stimulates the chromaffin tissue of pheochromocytoma.

Examination of Gastric Contents for Tubercle Bacilli.—Banyai has used gastric aspirations in the search for tubercle bacilli since 1933. He is convinced that bacteriologic examination of the fasting gastric contents can be used to advantage in tuberculosis work for the following purposes: (1) in clinical diagnosis; (2) for the management of tuberculous patients; (3) in follow-up examinations of patients presumably recovered from tuberculosis; (4) for bacteriologic screening of persons in close contact with persons suffering from tuberculosis, and (5) for the study of persons roentgenograms of whose chests show abnormalities. It is the author's practice to pool individual gastric specimens obtained on successive days. The pooled specimens are prepared for culture or animal inoculation as a single specimen. The author discusses the possible sources of tubercle bacilli in the fasting gastric juices and shows that the examination is of value in pulmonary as well as in extrapulmonary forms of tuberculosis. In 7 of 22 patients with tuberculosis of bone and joint, without demonstrable active tuberculous involvement in the lung, tubercle bacilli were found in the stomach juice. The usefulness of this method was tested in tuberculous lymphadenitis, pleurisy with effusion, renal tuberculosis and lupus vulgaris. The results show that examination of the fasting gastric contents is of importance in establishing the diagnosis in a substantial percentage of such cases.

Leukemia and Pregnancy.—Williams reviews the literature on the coexistence of leukemia and pregnancy and adds 2 cases, which bring the total to 90. One of the cases concerned a woman in whom chronic myelogenous leukemia was complicated by pregnancy. This woman is still living a year after delivery. The other case is unique in that it is the first reported instance of monocytic leukemia associated with pregnancy. This woman was delivered by cesarean section two hours after spontaneous rupture of the membranes. The baby was normal. The mother died eight days after delivery. Postmortem examination revealed acute monocytic leukemia, with leukemic infiltration of all organs, monoblastemia, petechial hemorrhages of all organs, acute ulcerative gingivitis, multiple infarcts of the spleen and pulmonary edema. In the first patient, it seems probable that the leukemic state antedated conception and gestation by several months, while in the second instance onset during pregnancy seems likely. The course and the findings at necropsy in the patient with acute monocytic leukemia, though unique in obstetric literature, are in close accord with previous reports; the natural history of the disease was apparently not altered by the complicating pregnancy. The medical management of both of these cases was of a supportive nature. Leukemia is not transmitted from mother to child.

Neutron Therapy.—Stone says that neutrons were first used in the treatment of human cancer in 1938. The late effects from the irradiation of animals with neutrons are greater in proportion to the early effects than would be expected from previous experience with such effects from roentgen irradiation. Neutron therapy has resulted in such bad late sequelae in proportion to the few good results that it should not be continued. Eighteen patients have been kept alive, but none of them are free from distressing late effects. Any one contemplating the use on patients of new radiations such as multimillion volt protons, beta rays and roentgen rays should study the relative biologic effectiveness of them by late reactions as well as by acute early ones.

Roentgen Changes Produced by Diffuse Torulosis in the Newborn.—According to Neuhauser and Tucker calcification of the brain is rarely observed on roentgenograms made during the neonatal period. The exact nature of the intracranial calcifications that were occasionally observed went without explanation until the work of Wolf, Dyke and associates demonstrated that intracerebral calcification was frequently associated with toxoplasmic encephalomyelitis. Another cause for calcification in the brain in the neonatal period was demonstrated recently by Landing and Farber, who described the postmortem finding in an infant 7 weeks of age of a diffuse meningoencephalitis caused by Torula histolytica (Cryptococcus neoformans). Their studies demonstrated that the combination of degeneration of the brain, meningoencephalitis, calcification within the brain, chorioretinitis and generalized visceral involvement found so characteristically in infants with toxoplasmic infection may be produced by another infectious agent. Since the discovery of torulosis in that infant, the occurrence of the disease has been proved at postmortem examination in 2 more infants in the same laboratory. This paper is concerned primarily with a description of the roentgenologic changes in these 3 patients. Each showed evidence of mild hydrocephalus on roentgenographic study and diffuse punctate and confluent calcification of the severely degenerated brain. The calcification resembles that seen with toxoplasmic encephalitis. Enlargement of the liver was present in each patient and enlargement of the spleen was striking. Two patients showed inflammatory and granulomatous lesions in the lungs, and 2 showed nonspecific submetaphysial decalcification of the long bones. In each patient the infection was evidently acquired in utero, during delivery or early in the neonatal period. The damage produced by the fungus was severe, and fatal within a few weeks after birth.

Toxoplasmosis with Intracranial Calcifications.—Fisher and Wilson report a white female infant who lived to be 17 months old and who showed the classical picture of congenital toxoplasmic encephalitis of convulsions, cerebral calcifications, chorioretinitis and hydrocephalus. Antibody neutralization studies carried out on the child's and the mother's serum showed both to have antibody reactions positive for Toxoplasma. Roentgenograms showing the unusual intracranial calcifications are presented. Since this child's disease was probably contracted from the mother, it is interesting to note that the only animals the parent had any contact with were a pet dog during the last two months of her pregnancy and a canary as a pet for one summer, two years before the child was born. Callahan reports that both of these animals are natural hosts of Toxoplasma.

Drip Anesthesia with "Pentothal Sodium."—Cottam presents his experiences in over seven thousand operations that were carried out with the patient under anesthesia induced by the intravenous administration of "pentothal sodium" alone or in combination. Major surgical interventions were carried out in 4,545 of the cases. "Pentothal" was used for major operations in such circumstances, as when surgeons would schedule a minor operation that would turn out to be a major one. It was soon realized that the postoperative course was smoother than after other forms of anesthesia. There were fewer cases of vomiting and gas pains and fewer instances of acute dilation of the stomach. The recovery period was shorter. When an operation was begun with patient under "pentothal" anesthesia and an inhalation anesthetic was added for better relaxation, the postoperative recovery was much smoother than if an inhalation anesthetic had been used alone. After that combination anesthesia was used widely. One of the most popular at the author's hospitals is intravenous administration of a combination of "pentothal sodium," oxygen, cyclopropane and curare. At first a 5 per cent solution was used, but when it was found that some patients slept for long periods afterward, weaker solutions were tried. Now the author never uses a solution that is stronger than 1 per cent, and in very young and very old patients 0.5 per cent. "Pentothal" given by syringe is dangerous and solution strengths above 1 per cent are not safe. The intravenous drip method with solution strengths of 1 per cent and below are not dangerous. The author outlines a safe preoperative and postoperative routine and stresses the advantages of intravenous anesthesia alone or in combination.

Placental Blood and Placental Extract in Wound Healing.—Cole used placental blood in combination with extract of placental tissue in chronic granulating wounds of varicose ulcer decubitus variety. Placental blood was collected aseptically in sterile pans. The blood was mixed with sterile jelly so that the consistency was that of a paste. The mass of red cells before being used was mixed with an extract of placenta. This extract was obtained by squeezing the placentas of the same patients whose blood was used. A number of illustrating case histories are presented. A comparative study of the pooled red cell mass and the placental mass demonstrates conclusively that the healing action of the latter is more potent. The patients on whom the preparation has been used were mostly people of advanced age who had wounds of varying periods of time. The substance greatly alleviated pain. Penicillin was tried in 1 patient both locally and parenterally with signal failure. The substance used proved to be superior. The fact that the placental mass produces better effects than red cells may be due to a greater amount of "growth hormone" and also perhaps due to a greater amount of the steroids, glycogen and vitamin C in placental tissue.

Reiter's Disease.—Lowman and Boucek report 5 cases of Reiter's disease. Four are typical cases with the classical triad of urethritis, conjunctivitis and arthritis. In the fifth patient the syndrome was incomplete, conjunctivitis being absent. Two of the patients presenting the complete triad responded to treatment with artificial hyperthermia and penicillin and promptly went into remission. These patients had been chronically ill for six and seven months respectively. Follow-up examinations after four and six months respectively showed no recurrence. If this favorable response to fever and penicillin can be obtained in other cases of Reiter's disease it will mean a substantial reduction in the morbidity of a protracted disease process.

Histoplasmin and Tuberculin Sensitivity in Wisconsin Students.—Dickie and Clark show that histoplasmin sensitivity among students at the University of Wisconsin reflects what is known of the geographic distribution of such sensitivity in the United States. A significant proportion of hilar and pulmonary calcifications seen in roentgenograms of the chest is not associated with tuberculin sensitivity. In this series 66 of 73 such calcifications in tuberculin-negative persons were associated with histoplasmin sensitivity. The incidence of pulmonary calcifications of the entire group surveyed in this study was 38.3 per cent in the students reacting only to histoplasmin and 9.2 per cent in those who reacted to tuberculin alone. Small pulmonary infiltrates indistinguishable roentgenologically from tuberculous lesions may be associated with histoplasmin sensitivity and not tuberculin sensitivity. The authors consider it erroneous to base a diagnosis of tuberculous infection merely on the roentgenologic detection of pulmonary calcifications or infiltrations.

Spontaneous Absorption of Congenital Cataract Following Maternal Rubella.—Ehrlich reports a hitherto undescribed development in congenital cataract following maternal rubella; namely, its spontaneous absorption, leaving only a membrane in its wake. Such absorption has rarely been seen in congenital cataracts of presumably different origin. A case in which the process occurred is described. Four other cases in which this process may have taken place, in 3 of which the mother had rubella during the early part of the pregnancy, are cited.

Carbamates in Leukemia.—This report by Skipper presents a simple and rapid technic for rough qualitative determination of the leukopenic action of a given agent, the mouse being used as the experimental animal. Results of hematologic studies with urethane, nitrogen mustard, roentgen rays, potassium arsenite and benzene are reported herein. The first phase of the hematologic screening technic entailed determination of the acute LD_{50} of the agent to mice by parenteral administration, isotonic sodium chloride solution, 10 per cent gum acacia, propylene glycol or peanut oil being used as the carrier. In the second phase of the study, mice were grouped and given injections at the LD_{50} level and at one half the LD_{50} level. Five mice from each group were killed for hematologic study at two and four or four and seven days after injection. In accord with general statistical practice, it is assumed that any group of animals having a mean leukocyte count of plus or minus 3 standard deviations from the control mean has been significantly affected by the therapy in question. On this basis, there can be little doubt that the leukopenic action of urethane, nitrogen mustard, roentgen ray, potassium arsenite and benzene has been demonstrated by the assay.

Para-Aminobenzoic Acid in Leukemia.—Zarafonetis and his co-workers deal with the results obtained in 10 patients to whom para-aminobenzoic acid was administered. Five of these subjects had chronic myelogenous leukemia; 3 had subacute myelogenous leukemia, subclassified in 2 as erythroleukemia, and 2 had chronic lymphatic leukemia. Para-aminobenzoic acid was placed in solution by conversion to sodium para-aminobenzoate with sodium bicarbonate. The final volume was adjusted to make a 10 per cent solution, which was administered orally to the patients in 20 cc. to 40 cc. doses (2.0 Gm. to 4.0 Gm.) every two hours, day and night. The solution was taken most readily in a small amount of fruit juice or ginger ale. Para-aminobenzoic acid, administered in large doses as sodium para-aminobenzoate, caused a striking lowering of the leukocyte count in 5 patients with chronic myelogenous leukemia and in 1 patient with subacute myelogenous leukemia. It caused less definite decreases of the white cell count in 2 patients with chronic lympatic leukemia, but the periods of administration may have been too short to obtain maximal effects. In every instance there was a prompt rise in the number of leukocytes when the administration was stopped. Although there was decrease in spleen size in some of the patients, the objective clinical improvement was but slight and temporary. Sodium para-aminobenzoate is not considered a practical adjunct to the therapy of leukemia at this time. It is hoped that studies of the cellular chemistry involved in the apparent inhibitory action of sodium para-aminobenzoate may yield information concerning the disordered metabolism of leukemic cells.

Glaucoma as Complication of Hysterectomy.—McCreery and Hansel report a woman, aged 61, who was operated on for a suprapubic mass extending to the umbilicus. This mass originated in the right ovary. There were a number of small fibroids in the uterine wall. The ovarian mass had become firmly adherent to the lower leaf of the mesentery of the ileum. The usual hysterectomy was performed. Since it was found impossible to free the tumor, it was removed with about 10 inches (25.4 cm.) of the ileum; an end to end enteroenterostomy was done. On the fifth postoperative day the patient complained of neuralgia-like pain over the right eye, which seemed to continue in spite of warm compresses and sedatives. On the sixth postoperative day the tension in the right eye was found to be 50 by Schiotz tonometer. The eye was definitely hard to finger tip pressure and showed deep scleral injection. The cornea appeared moderately hazy. On the basis of a diagnosis of glaucoma, treatment with physostigmine salicylate was instituted, and this controlled the tension in both eyes. Later, when the patient became sensitive to physpstigmine, therapy was changed to pilocarpine hydrochloride. Since the tension in the right eye remained rather high, a corneosclerectomy was done in this eye with good control of the tension.

Nitrogen Mustard at Hartford Hospital.—Wawro says that since July 1946 nitrogen mustard has been made available to the Hartford Hospital by the National Research Council for clinical use in selected cases of lymphoma, polycythemia vera and advanced cancer of the lung. This agent has been used on 27 patients. Experience has been limited to the use of methyl-bis (B-chloroethyl) amine hydrochloride, since there is less danger of venous thrombosis with this agent. The prescribed daily intravenous dose was 0.1 mg. per kilogram of body weight. Four daily treatments constituted the usual course, though occasionally treatment would be withheld on the third day when pronounced nausea and vomiting occurred. Established diagnoses in cases in which the treatment was used were Hodgkin's disease, lymphosarcoma, chronic lymphatic leukemia, mycosis fungoides, polycythemia vera, inoperable bronchogenic carcinoma and widespread carcinomatosis from breast and gastrointestinal tract. Favorable and dramatic clinical remissions in advanced and terminal cases have lasted from ten days to fourteen months. The best results were obtained in Hodgkin's disease, but significant palliation was achieved in lymphosarcoma, chronic lymphatic leukemia, mycosis fungoides and advanced metastatic bronchogenic cancer. Roentgen therapy is still the treatment of choice for localized lymphoma, since the margin of safety is greater and this therapy can be given locally. Once the disease becomes refractory to irradiation or too extensive for local treatment, nitrogen mustard suggests itself as a useful therapeutic agent.

Chronic Intestinal Upsets Due to Amebiasis.—Groff stresses that practitioners should be aware of tropical diseases in overseas veterans and should be on the lookout for amebic infestation in those who have chronic gastrointestinal upsets. In 6 patients (3 soldiers, 2 sailors and 1 civilian) who were observed in the course of nine months, there was soreness of the abdomen, more especially over the cecum. These men had recurrent bouts of profuse, watery and occasionally bloody diarrhea, with eight to ten bowel movements daily. Diarrhea lasted twenty-four to seventy-two hours. Following diarrhea, there would be a period of relief of four to seven days, although they continued to have "irritable colon," with the desire to defecate after ingestion of food. Two of the men had occasional bloody rectal discharges. Four of the 6 patients had had an examination of a warm stool specimen and sigmoidoscopy. Endamoeba histolytica was found in the material obtained by the sigmoidoscope in only 1 of 4 cases. This was attributed to the fact that these men had received a mixture of camphorated opium tincture and bismuth compound for an acute attack just prior to the examination. These patients were given a trial course of antiamebic therapy, with prompt relief of the symptoms. Treatment of amebiasis varies in different clinics, but emetine hydrochloride is chiefly used in the dysentery or abscess forms of amebiasis, and not only does it possess antiamebic effect, but seems to act as an antispasmodic and antipyretic drug. Not only should amebic infestation be considered in the presence of intestinal complaints, but invasion elsewhere in the body, such as in the liver, gallbladder, lung or brain, should also be watched for.

Hypofunction of Adrenals During Early Life.—Jaudon emphasizes that the pediatrician should acquaint himself with the life-sustaining functions of the adrenal glands and should think of the possibility of temporary hypofunction of these glands when dealing with infants who present symptoms of protracted gastrointestinal disturbances, who fail to gain weight, who have an unexplained tendency to dehydration and who respond unsatisfactorily to the accepted therapeutic measures. The author presents 5 cases which demonstrate the existence of a fractional and transitory disturbance in adrenal function. The patients required administration of desoxycorticosterone acetate and salt for long periods to sustain life. Low carbon dioxide-combining power, elevated nonprotein nitrogen, and moderately low serum sodium chloride during periods of hemoconcentration were present in all cases. The clinical course before, during and after hormone therapy is evidence suggesting a temporary absence or physiologic low supply of the desoxycorticosterone factor of the adrenal cortex.

Sclerema Neonatorum.—Hughes and Hammond define sclerema neonatorum as an uncommon disease characterized by a diffuse, rapidly spreading, nonedematous, tallow-like hardening of the subcutaneous tissue of infants in the first few weeks of life. The skin in involved areas cannot be picked up, and the subcutaneous tissue seems bound down to subjacent muscle and bone. The involvement usually starts on the buttocks, thighs or trunk, but may spread to involve any area of the body save the soles, palms and genitalia. The affected infants often have other diseases associated with the process, such as pneumonitis, enteritis, intracranial hemorrhage or congenital heart disease. Many show difficulty with respect to temperature control and little tendency to spontaneous movement. The disease is usually discovered in the first few days after birth. The course is usually rapidly downhill with a fatal termination. In reviewing the cases reported in the literature as sclerema, the authors have eliminated all cases which seem more typical of subcutaneous fat necrosis, scleroderma or hydrops. The significant findings from the 28 cases reviewed are as follows: Average age of onset was four days with extremes from birth to 70 days; 25 per cent of the mothers were ill at the time of delivery; all but two deliveries were spontaneous; average birth weight was 2,800 Gm., with variations from 2,150 to 4,100 Gm.; the majority of infants exhibited abnormal behavior at birth, weakness and cyanosis being the most common symptoms; almost all children had difficulty with control of body temperature and evidences of other complications besides sclerema; 75 per cent died, with the average age of death 10 days; at necropsy of 11 infants thickening of connective tissue bands was the most common observation. The authors present detailed histories of 3 additional cases. Various etiologic theories have been proposed. Most of the evidence favors the hypothesis that sclerema neonatorum may be a manifestation of severe shock in early infancy and that the hardening of fat and thickening of collagen fibers in the subcutaneous tissues may result from insufficiency of peripheral circulation.

Survivors of Kernicterus Due to Rh Sensitization.—Lande reports 8 cases of kernicterus due to Rh sensitization observed at the Dixon State Hospital. The development of these children was followed for several years, the oldest now being 11½ years of age. These cases fall clinically into four distinct groups: In the first, there is a generalized athetosis due to destruction in the corpus striatum and globus pallidus. In the second, there is persistent spasticity from involvement of the pyramidal and extrapyramidal systems. In the third, ataxia and disturbance of balance are the predominant features suggesting cerebellar degeneration. In the fourth, atonic diplegia from involvement of the extrapyramidal tract dominates the picture. Most patients show combinations of signs of all these four varieties. In some of the cases, there was a change from spasticity to hypotonia. In addition to these motor disturbances, a considerable percentage of the patients exhibit cranial nerve signs. Four patients were deaf; one of them was blind and deaf; another had a transitory blindness. Several patients had ocular signs suggestive of transitory or permanent involvement of the third or sixth cranial nerve nuclei. The mental development in most of these cases was retarded from the beginning and soon came to a standstill. The part played by damage to the liver in the causation of icterus gravis neonatorum is now generally recognized. Why the destructive process has a predilection for the nuclear masses of the brain is still open for discussion. That kernicterus develops only in a certain percentage of patients with malignant jaundice of the newborn suggests that in addition to the Rh allergy of the mother there may be another constitutional hereditary factor predisposing the fetal brain to damage. There are families in which the nervous system of the members seems to be abnormally susceptible to damage from infections and toxic or emotional disturbances. The author reviews the family histories of his 8 patients and finds that high intelligence but predisposition to nervous breakdowns and mental depression were found in some of the parents. Mongolism, encephalomeningitis and other cases of kernicterus were found among the siblings.

Cornelian Corner: Healthy Parent-Child Relationship.—Bartemeier describes the formation and aims of the "Cornelian Corner," an organization of pediatricians and clinical psychologists the chief aim of which is the promotion of healthy parent-child relationships. The organization is named for Cornelia, the mother of the Gracchi. It aims to reestablish the practices in infant care which were in vogue when babies were born in the home. It was customary for mothers to nurse their babies, to feed them as often as they seemed to need nourishment and to give them a great deal of mothering. Fathers commonly assisted in the care of their infants, and brothers and sisters had free access to the new baby. The separation of infants from their mothers and fathers in our modern hospitals is unhealthy for both the parents and their offspring, and it prepares for difficulties in the subsequent parent-child relationship. Natural mothering establishes the first human relationship, which becomes the foundation for all other subsequent relationships. Through its efforts to have the newborn infant in the same room with its mother from the time of birth, the Cornelian Corner hopes to make it possible for the father of the child to visit as often as he can. It encourages him to hold his infant so that he, too, may begin to love his child as early as possible.

Preventive Measures for Atomic Explosion.—Bauer estimates that casualties will be counted in the tens of thousands. With the large number of burns and mechanical injuries expected, the immunization of the population against tetanus should be considered. Disruption of water supply and sewage disposal systems would suggest immunization against organisms infecting the digestive tract. The demand for blood transfusions suggests the advisability of pretyping the population and devising some method of indicating each person's type. The psychologic preparation of the public is of vital importance. False complacency through overoptimism will lead to a severe psychologic shock. Overemphasis of the devastation produced may lead to panic. Since light-colored loose clothing furnishes good protection against flash burns, the cooperation of clothing designers may be important. If the bomb is detonated high in the air, residual radioactivity will not be a problem. Casualties from immediate radiation have in the past comprised between 15 and 20 per cent of the patients treated. Good nursing care and use of blood transfusions, antibacterials, vitamin C and intravenous administration of dextrose and sodium chloride will be the most important factors in the treatment.

Screening Methods for Detection of Uterine Cancer.—A year ago McSweeney and McKay started a clinic for the early detection of cancer of the uterus at the Boston City Hospital. All departments of the hospital have been requested to refer as many women over 35 years of age as possible to the gynecologic clinic for "screening," which consists of a gynecologic history, with special attention to abnormal bleeding and vaginal discharges, a pelvic examination, a speculum examination and a vaginal smear. The last is most valuable as a test to determine patients that may require diagnostic curettage or cervical biopsy not otherwise indicated by the history and pelvic examination. In one year 639 patients were examined and 934 smears studied. Of 54 cases of cancer, 51 were diagnosed correctly by smear. Six cases of carcinoma, which might otherwise have been neglected, were detected by the vaginal smear technic, and 6 others were detected simultaneously by biopsy and smear.

Epilepsy Secondary to Intracranial Tumors.—White and his associates state that of 1,130 patients admitted to the Massachusetts General Hospital with epilepsy in the decade 1935 to 1944, inclusive, 240 had seizures arising from an area that could be localized by clinical signs, pneumography and electroencephalography. In all these cases the disease has been verified by exploratory craniotomy. The authors have divided this series into two groups: 160 cases of cerebral compression caused by intracranial tumors and 80 cases of acute or chronic epilepsy due to trauma or infection. Epilepsy is a common complication of brain tumors, accompanying approximately one out of every three such growths when the hemispheres are compressed or invaded. When a middle-aged patient complains of epilepsy of recent onset, occurring without previous trauma or infection, tumor of the brain is the most probable diagnosis. The tumor with accompanying early seizures is most likely to be growing slowly and situated near the surface of the hemisphere, either a meningioma or astrocytoma or an oligodendroglioma. If attention is paid to this important sign, an early search can be made for the lesion and radical excision attempted before the patient has reached the critical advanced stage. Chances of "curing" the convulsive state, however, are not good. In 33 cases of astrocytoma no patient has had an apparent cure, and in only 8 have the frequency and severity of the seizures been significantly reduced. Epileptic convulsions have continued in the remaining 22, owing to the surgical difficulty of totally eradicating the diffusely invasive forms of astrocytoma or avoiding the irritative action of the contracting scar after radical removal of these tumors. Three others suffered their first convulsions after operation. Of 4 patients with oligodendroglioma, 1 has been entirely relieved of his seizures and another greatly improved. In the more malignant glioblastoma multiforme and metastatic carcinoma of the brain benefits obtained persisted for only a few months. Lesions of the basal ganglions and third ventricle are infrequently a cause of epilepsy. Tumors limited to the posterior fossa usually produce atypical seizures associated with transitory attacks of vertigo, syncope and irritation of the lower cranial nerves. This syndrome, classified as "ictus subtentorialis," is caused by compression of pons or medulla. In the rare case in which typical major seizures occur, it is usually found that a medulloblastoma has implanted itself above the tentorium.

Treatment of Alcoholic Addicts.—Young reports on study of 2,275 sanitarium cases of alcoholism, the majority of which were observed and studied for at least four weeks. He found that every addict to alcoholism has a psychiatric problem, which varies in intensity from case to case. The nutritional and vitamin imbalance produced by alcoholism is most important, and improvement in the nutritional state is frequently accompanied by improvement in the psychiatric symptoms. The vast majority of alcoholic addicts should be institutionalized for study and treatment. Every alcoholic addict given the proper help can get well and stay well, provided that he accepts the fact that under no circumstance can he take an alcoholic drink of any type.

Diagnosis of Carcinoma of Lung.—Woodman stresses that early diagnosis depends on efforts to shorten the time between the appearance of first symptoms and diagnosis (forty-five weeks) and the period between the patient's first seeking medical care and the final diagnosis (seventeen and a half weeks). Once the patient is in a hospital where the diagnostic team is available, the time of arriving at a diagnosis is not long. In 105 patients it averaged ten days. The author reviews 116 cases of primary carcinoma of the lung. The average age of the patients was 55 years. Ten of the patients—that is, less than 10 per cent—were women. The chief symptoms were: chronic productive cough, pain, loss of weight, weakness and dyspnea, with bloody sputum and frank hemoptysis generally late symptoms. The author discusses the diagnostic value of roentgenoscopy, bronchoscopy and biopsy. Means of hastening the diagnosis of primary carcinoma of the lung include earlier investigation of a cough of unknown origin. Patients with a cough of more than three weeks' duration should have roentgen examination of their chests. The diagnostic advantages of a hospital where the internist, roentgenologist, bronchoscopist and thoracic surgeon can act as a team in making the diagnosis should be resorted to early.

Transorbital Lobotomy.—Jones and Shanklin direct attention to the transorbital approach to the brain, which was developed by Framberti on the basis of the work of Moniz and others. The authors report 41 cases in which Freeman's method of transorbital lobotomy was employed. Beneficial effects were produced in four fifths of the 35 patients in whom more than one month had elapsed since operation. Transorbital lobotomy has produced no deaths or major postoperative complications. A unilateral ptosis of the upper eyelid was produced in 4 cases, but this gradually disappeared without residual paralysis. Prefrontal lobotomy can be performed safely by means of the transorbital technic. It does not produce demonstrable postoperative disability and may cause the disappearance of the physiologic and psychologic components of tension. Transorbital lobotomy may be considered for the patient not permanently aided by electroshock but in whom a major lobotomy might not be indicated. Transorbital lobotomy parallels the more radical procedure in that its postoperative course in successful cases is accompanied by decided relief from anxiety and inner turmoil.

Effect of Tetraethyl Ammonium Chloride on Acidity in Peptic Ulcer.—Ferrer points out that investigations by Acheson, Moe, Lyons and their co-workers indicate that tetraethyl ammonium salts produce an effective block of all autonomic nerve impulses, both sympathetic and parasympathetic, and that this block occurs at the autonomic ganglions. One of the many effects of this block is reported to be a decrease in gastrointestinal motility and in the volume and acidity of the gastric juice. An investigation was undertaken to determine whether the excessive night secretion in patients with peptic ulcer could be prevented by vagus nerve block with tetraethyl ammonium chloride ("etamon chloride"). The block produced by tetraethyl ammonium chloride is not a pure vagal block but a combination of vagal plus sympathetic block. The drug prevented excessive night gastric secretion and acidity in twelve of seventeen tests of patients with peptic ulcer. Intramuscular dosage of approximately 20 mg. of tetraethyl ammonium chloride per kilogram of body weight is usually adequate to produce this effect if repeated at intervals of four hours but is not uniformly adequate at intervals of six hours. When the compound was given at four hour intervals, excessive night gastric secretion and acidity were inhibited in 6 of 7 patients with peptic ulcer. No serious toxic or side effects were noted. Transient fall in both systolic and diastolic blood pressures was noted after administration of the drug. Therapeutic trial of the effect of tetraethyl ammonium chloride on the symptoms and healing of peptic ulcers is warranted and will be undertaken.

Transition of Pancreatic Edema Into Necrosis.—Popper and his co-workers show that the usual pathogenetic mechanism of acute pancreatitis is a block either by stone or spasm at the papilla of Vater in the presence of a common channel between common bile duct and pancreatic duct. The subsequent increase of pressure in the duct system and the intraductal activation of pancreatic juice are regarded as causes of acute pancreatitis. The presence of a common channel was observed in nine tenths of the cases of pancreatic edema, of acute pancreatitis and of pancreatic necrosis. This, together with the observation that transition of pancreatic edema into acute pancreatitis occurred, suggested that these processes were related. The method used by the authors for experimentally producing pancreatic edema consisted in stimulation of external pancreatic secretion by intravenous injection of a large dose of secretin after ligation of the main pancreatic duct or of the main and accessory ducts. Since the authors did not succeed in producing pancreatic necrosis by increasing or prolonging the edema-producing administration of secretin, it became apparent that pancreatic necrosis or hemorrhagic pancreatitis is not merely a later stage of pancreatic edema. Procedures such as obstruction of lymphatic drainage or of venous return from an edematous pancreas, or the production of shock in dogs with edema of the pancreas, did not elicit necrosis. Positive results were obtained with temporary occlusion of the main pancreatic artery, if performed while edema of the pancreas was present. The important fact is that temporary local ischemia is able to transform a clinically harmless transient edema of the pancreas into hemorrhagic pancreatic necrosis. The clinical applications of these experimental observations are: 1. Local vasomotor changes may be responsible for the transition of pancreatic edema into pancreatic necrosis. 2. The extent of local vasomotor changes may determine the degree of pancreatitis. 3. If acute pancreatitis is diagnosed or its presence is suspected, everything should be done to make a presumably existing edema disappear and to avoid local ischemia. To make the edema disappear it seems best to give spasmolytics which will relax the sphincter of Oddi, to prevent any stimulation of the external secretion of the pancreas and to attempt its active inhibition. Local vasomotor changes are nothing unusual after surgical procedures, and this may in part explain the poor results of surgical intervention in acute pancreatitis.

Infusions of Protein Hydrolysate.—The solution used by Weinstein was a 5 per cent protein hydrolysate in distilled water. The source of the protein was bovine blood, collected under sanitary conditions, processed and hydrolyzed by means of a pancreatic enzyme preparation. The hydrolysate is then treated to remove harmful constituents and diluted to the desired concentration. Filled sealed bottles of the solution are sterilized by autoclaving and packaged in 500 or 1,000 cc. containers. In 2,003 consecutive intravenous infusions of 1,000 cc. each, in 320 preoperative and postoperative surgical patients there were 0.72 per cent reactions. Four hundred and twenty subcutaneous infusions of 1,000 cc. were given at a rate of 6.25 cc. per minute in 126 patients without local difficulties. One hundred and seventy intramuscular injections of 1,000 cc. of protein hydrolysate in 78 patients at a rate of 33 cc. per minute show rapid absorption in three hours, no irritations or local reactions, no failure of absorption and a negligible amount of pain or discomfort. A comparison of intravenous, subcutaneous and intramuscular infusions is made, and the advantages and disadvantages of each route are discussed. Bovine protein hydrolysate is a safe parenteral fluid for patients who require proteins by intravenous, subcutaneous and intramuscular routes.

Streptomycin in Tuberculous and Mixed Infections of Genitourinary Organs.—Redewill and Potter review the literature and their own experiences with antibiotics and chemotherapeutic substances in the treatment of infections, particularly of tuberculosis of the genitourinary tract. Dosage of streptomycin should be small in treating infection of genitourinary organs because antibiotics are rapidly excreted by the kidneys and 1 Gm. daily produces 100 micrograms per cubic centimeter, which is ample to check infections. Streptomycin has a delayed sustained action if given only twice a day for forty-five to sixty days, with two to three weeks' vacation, provided that urine is kept alkaline and there is no gross obstructive pathologic change in the urinary tract. A simplified method of antibiotic assay is reported. Penicillin will cure most coccic infections; streptomycin mostly gram-negative rod and coccic as well as tuberculosis infections. Penicillin and streptomycin are symbiotic. Still greater symbiosis exists between penicillin and sulfadiazine and streptomycin and the sulfones. The most active and least toxic of all is the combination of streptomycin and "promizole" (4,2'-diaminophenyl-5'-thiazolylsulfone). Iontophoresis, quartz light and vitamins are necessary adjuncts in treating tuberculosis of the urinary bladder. Vesical and other urinary tract ulceration will heal more rapidly with increased nitrogen intake if the average protein level is low. Of 22 patients with tuberculosis of the genitourinary tract, 2 showed no improvement, but the others were either improved or apparently cured. This group included cases of tuberculous cystitis, nephritis and prostatitis. The authors also report 120 cases of acute and chronic nontuberculous urologic infection. Their percentage of cure and improvement was highest of any reported in the literature. They did not use streptomycin in cases in which it was to be expected that streptomycin fastness would develop, and they used in combination sulfonamide compounds, streptomycin and penicillin.

False Positive Serologic Reaction.—Love emphasizes that one serologic test, be it complement fixation or flocculation or precipitation, does not suffice for a diagnosis of syphilis. The test is subject to error, human, inherent, and of interpretation. Most biologic false positive reactions will be encountered in the following circumstances: (*a*) There has been vaccination for smallpox within the three preceding months, especially with "take." (*b*) Certain febrile diseases, the more important of which are malaria, infectious mononucleosis, virus pneumonia, influenza and mumps. Many other diseases are capable of producing biologic false positive serologic reactions, but are of less importance because of the uncommonness of the disease itself or a small incidence of false positive reactions resulting therefrom. Included in this latter group are typhus, leprosy, chancroid, lymphogranuloma venereum, Weil's disease, relapsing fever, rat bite fever, Rocky Mountain spotted fever, disseminated lupus erythematosus and septicemia. The author discusses technical errors, false positive reactions of the newborn, paradoxical false positive reactions and the general biologic false positive reaction in spirochetal, virus and other diseases. False positive serologic reactions in the spinal fluid have been reported in brain tumor, encephalitis and malaria and mumps. These are rather rare, especially in their relationship to false positive reactions in the blood.

Postpartum Cervix.—Sheets examined microscopically small pieces of tissue from cervix uteri, removed in the course of repair immediately following delivery in 200 consecutive cases. Decidual reactions occurred in 40 per cent of the specimens. Portions of Gartner's duct were observed in specimens from the cervical rim in 2 per cent of all instances. Proliferation of unripened squamous cells, marginally invading columnar epithelium or stroma, was seen at a rate of 12 per cent and produced patterns described by Novak as "epidermization." "Metaplasia," or rather atypical abberant epidermoid epithelium, appeared in glands or in areas replacing surface columnar epithelium or in continuation of normal squamous epithelium with sufficient frequency (71 per cent) to be considered as not unusual during pregnancy. Benign hyperplasia was observed in less than 10 per cent of all specimens. Intraepithelial preinvasive cancer occurred only in the presence of invasion in other parts of the specimen. Clinically unsuspected, grossly not demonstrable invasive carcinoma of the cervix uteri occurred twice in a series of 200 cases. No clinical symptoms appeared in these histologically proved cases during six months of observation following delivery. The frequency of normal and abnormal tissue behavior in the cervix during pregnancy or immediately following delivery cannot be correctly evaluated on the basis of clinical observation alone, but requires microscopic examination.

Occupational Medicine.—Belknap shows that lead is the most common toxic dust and that mercury poisoning may mimic intestinal flu. Cadmium fumes attack the alveoli. Benzine, although a cheap solvent, is a dangerous hematoxin. Carbon tetrachloride is a fatal nephrotoxin and arsine is more deadly than cyanide. Occupational medicine is as broad as internal medicine. Physicians should familiarize themselves with the technics and hazards of industry.

Substance in Serum and Platelets That Stimulates Suprarenal Medulla.—Reid found that in the serum of the cat and in extracts of the buffy coat of horse blood there is a diffusible, relatively heat-stable substance which, when injected into the arterial supply of the adrenal gland of the cat, causes an increase in blood pressure and heart frequency and contraction of the denervated nictitating membrane. These effects are due to the liberation of epinephrine from the adrenal gland. The active substance acts directly on the cells of the medulla and not through the preganglionic fibers. The activity cannot be attributable to histamine, potassium, adenyl compounds, hydroxyphenethylamine or a choline ester.

Trauma of Hand.—Duncan reports on 42 consecutive cases in which flexor tendons were divided within their sheaths. Here primary repair holds out infinitely better prospects of functional recovery than delayed procedure. If repair of a divided tendon is delayed six months or more the muscle belly of that tendon may have undergone such changes that repair by graft may offer little prospect for good function. It is wise under these circumstances to transplant to the damaged finger a tendon with a fully functioning muscle belly. He also reports on tears of the extensor tendons around the terminal interphalangeal joint. The loss of controlled apposition of the pulp of the index or middle finger to the pulp of the thumb is a handicap to any precision worker. In the middle and little fingers the loss of terminal joint movement adversely affects the power of grip so essential to heavy work. This report is based on experience in treating 60 of these injuries. Open operation on the tears has revealed *two main groups of mallet finger:* 1. The tendon insertion at the dorsal margin of the base of the terminal phalanx is avulsed with a fragment of bone. 2. The nonfracture type of mallet finger is caused by a tear of the extensor tendon at some point between its insertion and the triangular fascia of Bunnell. In mallet finger the flexion deformity of patients with synovial damage was roughly twice that of those that had not. The amount of active movement recovered was on the average 20 per cent higher in cases in which there was no damage to the synovium. The operative technic of treating mallet fingers, based on the recognition of the different types of lesion, can offer the patient a useful finger with the minimal degree of flexion deformity.

Postoperative Adhesions Caused by Talc.—Mackey and Gibson report the case of a woman, aged 74, in whom splenectomy was followed thirteen days later by a second operation because of continued bleeding into the alimentary tract. The second operation disclosed extensive dense adhesions. Histologic evidence is presented that these arose as a result of deposition of small amounts of talc at the time of the first operation.

Suspected "Tuberculosis" Proved to be Siliceous Granuloma.—The case presented by Smith had been reported previously as an example of a rare coexistence of carcinoma and tuberculosis in the same organ. The diagnosis of tuberculosis was made on histologic grounds, despite failure to demonstrate acid-fast organisms in the sections. Roberts in 1947 proved that granulomas occurring in the fallopian tube, with a histologic picture closely resembling tuberculosis, may be siliceous and not tuberculous: these foreign body granulomas apparently follow the introduction of talc (surgical gloves) into the peritoneum. Smith reinvestigated his case and gained the impression that the original diagnosis of tuberculosis was inaccurate and that of siliceous granuloma more likely. The patient had undergone appendectomy five months prior to hysterectomy for carcinoma of uterus. Microscopy revealed the presence in the fallopian tube of a pseudotuberculosis granuloma with giant cells containing doubly refractive material, almost certainly surgical talc.

Traumatic Arteriovenous Fistula.—Twenty-six patients with traumatic arteriovenous fistula were admitted to a peripheral vascular and nerve injuries unit in Edinburgh between 1942 and 1946. There were twenty-seven fistulas in 26 patients. An important factor in the diagnosis was the changes that were elicitable in pulse rate and diastolic blood pressure on digital occlusion of the fistula. The heart was not, as a rule, enlarged, though a postoperative diminution in size was observed. Operative closure of the fistula was delayed until the collateral circulation was established and adequate. The usual operation was quadruple ligation and excision of the sac, and an associated nerve injury, if present, was dealt with at the same time. The late results of treatment are considered in 23 patients who, with one exception, were gainfully employed. Good functional results were seen in the cases involving a lower limb, in which the peripheral pulses returned whatever the level of arterial ligation. Some patients had intermittent claudication of moderate degree, and a few had residual swelling, probably due to venous obstruction. In the cases involving the neck the residual headache and giddiness could not be explained satisfactorily. The results in the upper limbs were complicated by the associated nerve lesions. The real evidence of successful treatment will probably be obtained in ten to twenty years' time, when the vessels begin to lose their resilience.

Residual Symptoms After Thyroidectomy.—Martin points out that patients who have undergone thyroidectomy for Graves' disease (primary thyrotoxicosis) frequently retain symptoms such as nervousness, palpitations, sweating, tremor and lability of the pulse rate on emotion or exertion, besides some of the ocular signs of thyrotoxicosis. The symptoms are often loosely termed "residual signs of toxicity," but their origin has never been clearly demonstrated, though various causes have been suggested. The author studied 33 patients with primary thyrotoxicosis, in whom thyroid function was normal at intervals ranging from two and a half to ten years after thyroidectomy; 31 retained symptoms at the time of follow-up. Ocular signs were the only true residua of primary thyrotoxicosis. Other symptoms were attributed to constitutional factors, to the emotional effect of the disease and operation or to causes unconnected with either.

Multiple Papillary Adenomas of Intestine.—Aitken and Brown report a man, aged 39, who first presented symptoms in 1934 with the loss of "2 pints of blood" per rectum. He attributed this to prolapse of the bowel, and in reducing this "a dozen small grapelike structures" came away. From that time on he lost blood on approximately six occasions per year. In 1946 after a loss of blood he was examined by sigmoidoscope, and a large papilloma was observed in the sigmoid colon. He continued to lose blood from time to time until October 1947, when he was seized with attacks of violent colic. These attacks were unrelieved by sedatives and were followed by vomiting and dull aching pain in the region of the umbilicus. At operation slight distension of the large bowel leading to a giant papilloma (6 cm. in diameter) in the sigmoid colon was found. There was a large papilloma in the cecum (4 cm. in diameter). About the middle of the small bowel were two tumors (2.5 cm. in diameter). Three additional freely movable papillomas were palpated in the small intestine. The papilloma of the sigmoid and that of the cecum were removed and at a second operation the papillomas of the small bowel were removed. The patient recovered. The authors review the literature and stress that the incidence of papillomas in necropsies varies from 4 to 6 per cent. Such tumors are much more common in the large than the small bowel and are distributed equally between the sexes. Papillomas occur in three forms: smooth polyp, villous papilloma and intestinal polyposis. The commonest symptom is bleeding. Intestinal polyposis is a hereditary disease. Thirty per cent of intestinal papillomas become malignant. The treatment is entirely surgical and consists of either local destruction through the sigmoidoscope, enterostomy and removal of the polyp or colectomy.

Schönlein-Henoch Syndrome.—Of the 12 patients with the Schönlein-Henoch syndrome reviewed by Gairdner all but 1 were observed by him personally. Ten of the 12 patients were children between 4 and 15 years, and 2 were adults of 40 and 48 years. Previous authors have also found the condition predominantly in childhood. Ten of the 12 patients were male. There is a great variety in the mode of onset, and symptoms from any one of the three sites, skin, intestine or joints, may usher in the illness. A rash was present in all 12 cases. Gastrointestinal symptoms were present in all but 1 of the patients. Eleven of the 12 patients had colic; 8 had blood in the stools, and 6 had vomiting. Articular symptoms occurred in 10 of the 12 patients, varying from transient puffiness of a single joint to recurrent painful swelling of many joints. Nephritis was the most serious aspect of the condition. All except 1 patient showed some renal involvement; in 4 the hematuria was gross, and in 7 the hematuria was microscopic. The subsequent history of these patients shows that the nephritis may go on either to recovery, to latent nephritis, to chronic nephritis or to rapidly developing renal failure and death. The term Schönlein-Henoch syndrome is preferable to anaphylactoid purpura because purpura is neither uniformly present clinically nor the essential histologic feature of the exanthem. He assembles evidence to show that the Schönlein-Henoch syndrome, acute nephritis, rheumatic fever and polyarteritis nodosa together form a family of diseases. The pathogenesis common to this group is probably an antigen-antibody reaction, akin to that occurring in anaphylaxis and taking place especially in the endothelium of certain blood vessels. The commonest antigen is a derivative of the hemolytic streptococcus, although proteins derived from other organisms or from nonbacterial sources may also act. The blood vessels especially involved in the Schönlein-Henoch syndrome are the small vessels of the skin, intestine, synovia or glomeruli; in nephritis the glomerular capillaries, and in polyarteritis nodosa the medium-sized arteries and arterioles. In rheumatic fever the site of the reaction is less clear, but it is possible that here too the predominantly connective tissue damage is secondary to vascular lesions.

Immunization of Adults Against Diphtheria.—Scheibel and his associates point out that during the war the character of diphtheria changed in Denmark in that it not only became more virulent and had a higher mortality rate, but it also attacked proportionately more adults. It is assumed that the change in the ratio of the morbidity in adults to that in children is connected with the widespread immunization of children and the much lower incidence of immunization in adults. This explanation is further supported by the fact that almost all those who contracted diphtheria during the past few years either were not immunized or had not completed the immunization. The authors tried to learn: 1. Does immunization with four doses of 0.2 cc. give the same result as immunization with two doses of 1 cc., although the total antigen content is thereby reduced from 50 to 20 Lf units? 2. In cases in which it is necessary to employ a milder course, will it suffice by changing the intervals to give three injections of 0.2 cc. instead of four? 3. Can the usual routine dose be reduced from 1 cc. to 0.5 cc.? 4. Do the reactions decrease according to the size of the dose? On the basis of their observations the authors answer the first three questions in the affirmative. With regard to question 4 they found that severe reactions do diminish with decreasing doses, but this is only demonstrable in the group most likely to have reactions, and only when the dose is reduced to 0.2 cc. Accordingly, the ordinary routine method to be used hereafter by the authors will be twice 0.5 cc.—i. e., twice 12.5 Lf units—with a four week interval, and a year later another 0.5 cc. When smaller doses are indicated, three times 0.2 cc.—i. e., three times 5 Lf units—*at two week intervals* will be given, and a year later another 0.2 cc. The investigations suggest that the dose for mass immunization would eventually be diminished to twice 0.2 cc. followed a year later by a third injection of 0.2 cc.

Ovarian Disturbances After Thiouracil and Methylthiouracil.—Kopf and his co-workers found in experiments on rats that thiouracil and methylthiouracil cause changes in the maturation of the ovum which become manifest in the form of irregularities in the estrous cycle; estrus becomes less frequent. These experiments on animals are corroborated by observations on human subjects. Here, too, changes in the menstrual cycle develop under the influence of antithyroid substances. Menstruation has been known to become less frequent during treatment with methylthiouracil; cases have also been observed in which existing menstrual disturbances become regulated. This becomes understandable when it is recalled that transitions exist between *stimulating and injurious effects* of thyroid substances on the ovary. Menstrual anomalies seem to be elicited not by a definite thyroid disturbance but by the manner and degree of the changes produced in the ovary under the influence of the thyroid hormone. The authors believe that the changes in ovarian function which follow medication with the thiouracils are the result of the simultaneous existence of insufficiency and hyperfunction of the thyroid.

Aortography. G. Runström.—p. 934.
Psychosomatic Diseases in Children. S. Gunnarson.—p. 937.

Psychology versus Anatomy in Gymnastic Treatment of Brachial Neuroses and the Like.—Braatøy says that myalgia from overwork occurs predominantly in the antigravity musculature, as seen in office workers who use typewriters and other equipment placed too high for them. Rest from work, massage of the painful muscles and simple relaxation gymnastics are the rational therapy in these cases. Almost identical symptoms may be observed in patients not under similar working conditions when the antigravity muscles are used to check or lock the emotional reaction, as is more readily recognized if the patients are examined in a recumbent position, when the antigravity muscles have no physiologic functon to perform. If by suitable technic the hypertension in the antigravity muscles *is released emotional explosions will be released at the same* time. The release of emotional outbursts in myalgias given gymnastic treatment is preceded or accompanied by respiratory release. When such tensions have been fixed for a long period of time they characterize the patient's attitude, gestures and utterances. Series of ailments can be seen which range from myalgias due to overwork through conditions of blocked-up emotions requiring respiratory and emotional release to chronic entangled neuroses calling for systematic psychoanalysis.

Urethane Treatment in Leukosis. One Year's Experience.—Definite but transient improvement was seen in 15 out of 23 patients, mostly with chronic lymphatic leukosis, after treatment with urethane. *Half a year after treatment only* 4 patients continued improved; 10 patients died during the first half-year. In evaluation of the results improvement in the general condition, disappearance of splenic and glandular enlargement and normalization of the blood picture must be considered, *in the order named. The sedimentation reaction and as far as* possible variations in basal metabolism are also followed. The treatment must be highly individualized. The effect of treatment with urethane in chronic leukosis, though like that following roentgen therapy, is as a rule of shorter duration and the by-effects are often more prominent. In suitable cases the treatment can be tried if for some reason roentgen treatment is not desirable, but the author has returned to roentgen therapy as the normal method after one year's test of treatment with urethane. In acute leukosis, in which roentgen treatment is most often contraindicated, treatment with urethane should be attempted if the patient is not too debilitated; transient improvement may result. In the terminal stages the effect of the two methods is about equally slight. There is every reason to continue the study of urethane and its problems. It is still in the experimental stage and only its relative harmlessness justifies its application in the clinic at this time.

Streptomycin Treatment in Alcaligenes Meningitis. H. Jelke.—p. 989.

Vitamin D_2 Therapy in Lupus Vulgaris.—Preliminary results of treatment according to Charpy in 26 patients with lupus of the mucous membrane are reported by Strandberg. In most cases the serum calcium was increased and in more than half the cases the weekly microscopic examination of the urine revealed red blood corpuscles, usually several times. Transient albuminuria appeared in one case; in another grave persistent nephropathy developed after four weeks' treatment with irradiated ergosterol preparation and has continued for *over three months with constant albuminuria and increased* blood pressure. In 3 patients there was a peculiar eye disorder not previously described in the literature, marked by hypertrophy of the conjunctiva, with some sensitiveness to light and a feeling of foreign bodies in the eyes; the symptoms disappeared when irradiated ergosterol was discontinued. To date no improvement in the mucous membrane has been seen. Vitamin D_2 therapy does not seem to act on lupus of the mucous membrane as it does on lupus of the skin. Because of the necessary laboratory examinations, the troublesome diet and the risk involved, hospitalization is required during the treatment.

Streptomycin Treatment of Infections of Urinary Tract.—Frisk reports on 27 cases of chronic infection of the urinary tract due to bacteria susceptible to streptomycin and wholly or partly resistant to penicillin and sulfonamide drugs. Streptomycin was used, and in 20 cases treatment with alkali was given simultaneously. The results were good in 20 cases, transitory in 2 and poor in 5. With an alkali reaction in the urine the chance of successful therapy is enhanced and there seems to be less danger of the development of resistance to streptomycin. In 4 cases recurrence set in after one to three months; on repeated treatment the urine became sterile again in 2. In most cases in which the urine became sterile sterilization occurred within twenty-four hours, and in no case later than after seventy-two hours. Anatomic defects and injuries and mixed infections lessen the possibility of good results, but attempted treatment with streptomycin is considered justifiable in these cases. Of the 18 patients at present free from bacteria 13 have been observed for over three months. In 3 patients, only 1 of whom was treated with alkali, resistance to streptomycin developed during the treatment. The fastness seems to be definite. In 1 of the cases, followed for a year, resistance continues. In 2 instances grave vestibular disturbance occurred after six days' treatment, which has now lasted for three weeks and two and a half months, respectively.

Streptomycin Treatment: Classification of Reports on Patients Treated in Sweden.—Lindgren and Sjögren discuss 290 of the 350 cases in Sweden in which this treatment was used up to December 1947. The main indications for treatment were infections of the urinary tract due to bacteria susceptible to streptomycin and Pfeiffer's and tuberculous meningitis. The cases of infections of the urinary tract were mostly of long duration and refractory to other treatment; recovery followed in 68 per cent of the uncomplicated, 44 per cent of the complicated cases. In 10 of 29 cases of tuberculous meningitis the prognosis seems favorable. Eighteen of 22 patients with Pfeiffer's meningitis recovered. Total dosage of more than 15 Gm. gave better results than a lower dosage. When bacteria are demonstrable in the urine after seventy-two hours the prospect of overcoming the infection is slight. Complications of different kinds were seen in about one fourth of the cases. Vestibular complications occurred in 50 cases (17 per cent); their frequency increases with the dosage.

Thymectomy with Parathyroidectomy in Ankylotic Polyarthritis.—Leriche points out that if ankylosing arthritis involves only one joint, treatment by resection is possible, but if many joints are ankylosed, including those of the spine, only an operation that has a general systemic effect is justified, such as Oppel's parathyroidectomy. In 1928 Oppel reported that he had obtained improvement in 16 of 50 patients with ankylosing polyarthritis. Leriche performed Oppel's operation for the first time in 1928 and obtained spectacular success in a man who had been bedfast for a number of years. Since then the author has performed three or four parathyroidectomies for ankylosing polyarthritis every year. The majority of these patients have been followed for two or three years; in about half of them the improvement has proved lasting. The author also has had some failures, as have others who have employed this treatment. In 1936 the author combined parathyroidectomy with removal of a persisting thymus. Since then he has always searched for a persistent thymus in these patients and has found that the thymus frequently encloses one or two parathyroids. He reports the case of a man in whom thymectomy and parathyroidectomy was done in 1938 and who has been followed for nine years. The results were good. The author deplores that little attention has been given to his repeated reports on the favorable results of parathyroidectomy and thymectomy. He employs sympathectomy in cases of arthritis deformans.

Experimental and Clinical Study on Choleretic Action of a New Derivative of Sulfur. R. Kourilsky, B. Halpern and J. Martin.—p. 457.
*Treatment of Scabies with DDT. G. Garnier.—p. 458.

Treatment of Scabies with DDT.—Garnier says that since 1945 he has treated hundreds of patients, including young children, with a 6 per cent solution of dichlorodiphenyltrichloroethane (DDT) in an ointment base which is adherent, colorless and odorless. There were no signs of intolerance or toxicity and the treatment failed in only about 2 per cent of the patients. These favorable results are in contrast with those obtained by American and British authors, who not only failed to observe therapeutic and prophylactic results in scabies, but also called attention to the danger of intoxication and irritation involved in the use of DDT for scabies. Garnier says that if such undesirable effects occur, it is because the solvent in which DDT was applied was acetone, which facilitates cutaneous absorption. Since DDT is effective on contact, absorption is useless and not desirable. In the morning, after a soapy bath, the entire body, except the head, is painted with a 6 per cent solution of DDT in phthalic ethers. A second coat is applied ten minutes later. The patient then puts on his clothes. On the following morning the patient is given another soapy bath and all the underwear as well as the bed linen is changed.

*Action of Precordial Anesthesia on Pain and Electrocardiographic Changes of Angina Pectoris. L. Del Zar and J. Bronstein.—p. 17.
*Thiouracil in Therapy of Angina Pectoris and of Cardiac Insufficiency. B. Moia and J. Bronstein.—p. 25.

Precordial Anesthesia in Angina Pectoris.—Del Zar and Bronstein studied the effect of subcutaneous procaine infiltration of the precordial region on pain and the electrocardiographic changes caused by exertion in 22 patients with angina pectoris due to coronary sclerosis. There was exertion before and again five minutes after anesthesia. All patients had been given a clinical and an electrocardiographic diagnosis. Exertion elicited appearance of anginal pain in 10 cases, in 7 of which pain was either controlled or attenuated by procaine infiltration. In 1 case pain was elicited by effort after procaine infiltration anesthesia and not before it. Exertion produced changes of pathologic type in the electrocardiograms of 18 patients. Anesthesia failed to prevent or even to improve the electrocardiographic changes even in the cases in which pain was attenuated or suppressed by it. The authors conclude that subcutaneous procaine infiltration anesthesia of the precordial region either favorably modifies or controls anginal pain caused by exertion. However, it does not modify the changes in the electrocardiograms caused by exertion. These results suggest the value of precordial procaine infiltration as symptomatic therapy of anginal pain.

Thiouracil Therapy in Angina Pectoris and Cardiac Insufficiency.—Moia and Bronstein review the literature and give the results of their own observations. They observed a case of diffuse edema which appeared on administration of a thiouracil derivative and disappeared on discontinuation of the drug, frequent failure of the drug in angina pectoris and in cardiac insufficiency and sudden death after improvement in a patient with angina pectoris and aortic stenosis. They conclude that thiouracil should not be used in routine therapy for either angina pectoris or cardiac insufficiency. The drug is of value in selected cases, especially when the basal metabolism is initially high. Its administration should be discontinued if clinical improvement is either moderate or transient. Retention of water in cardiac insufficiency is a contraindication because of the danger of acute edema of the lung.

*Streptomycin Used for 18 Months in a Tuberculosis Sanatorium: Results in 170 Cases. E. Mordasini.—p. 605.
Two Injuries Caused by Sports. J. Heer.—p. 612.
Examination of Uncovered Slides with Cell Smears by Means of Dry Systems: Microscopic Technic. H. Scholer.—p. 613.
Action of Coagulation Promoting Phospholipoids and Calcium Chloride on Heparin During Coagulation of Blood and Plasma in Vitro. F. W. Kahnt.—p. 614.

Streptomycin in Tuberculosis Sanatorium.—Mordasini says that at two tuberculosis sanatoriums in Davos 170 tuberculous patients have been treated with streptomycin. Streptomycin is definitely indicated in the presence of acute hematogenic dissemination and in tuberculous meningitis. Such cases are generally seen and treated in hospitals, not in sanatoriums, but even for physicians on staffs of sanatoriums streptomycin is a valuable addition to the therapeutic armamentarium. The use of streptomycin has changed little in the established methods of sanatorium cure and in collapse therapy. The greatest value of streptomycin therapy is in making it possible to operate on many patients who otherwise could not be subjected to collapse therapy. The knowledge that there is a therapeutic weapon which is of great help in bronchogenic and hematogenic dissemination, particularly during surgical interventions either on the lungs or other organs, such as the kidneys, gives the physician a greater feeling of security and more freedom of action.

*Diagnosis and Treatment of Arteriovenous Aneurysm in Area of Hemispheres of Cerebrum. G. Weber.—p. 629.
*Etiology of Myeloid Leukemia from Point of View of Diaplacental Transmission. Kucharick.—p. 634.
Erosion of Eyes Caused by Calcium Spray. G. Papayannopoulos. —p. 635.

Arteriovenous Aneurysms in Cerebral Hemispheres.—Weber reports 15 cases of cerebral arteriovenous aneurysm in 10 men and 5 women treated at the neurosurgical clinic in Zurich. Symptoms of the disturbance were manifested at an early age, in 14 of the patients between the eighth and the twenty-eighth year. One patient only was 36 years old when first clinical symptoms were manifest. Four patients had epileptiform attacks only. Four patients had recurrent subarachnoid hemorrhages with or without hemiparetic symptoms. Six patients had epileptiform convulsions as well as recurrent subarachnoid hemorrhages. One patient, a girl aged 9, had monthly migraine with nausea, vomiting and a slowly progressing left hemiparesis. Four of the 15 patients complained spontaneously about an intracranial bruit, and a sound synchronous with the pulse was heard on auscultation of the head. Encephelography was performed in 11 patients, in 5 of whom the ventricular system extended toward the area of the vascular tumor; a displacement of one of the ventricles was demonstrated in 1 patient. In the remaining 5 patients the observations were doubtful. Diagnosis can be established by cerebral arteriography in the absence of aneurysmal bruit, enlargement of the heart and hemilateral exophthalmos. Treatment consisted of ligation of the internal carotid artery in 12 patients, in 10 of whom it was combined with roentgen irradiation. Roentgen irradiation alone was done in 1 patient and extirpation of the tumor in 1. In the majority of cases ligation of the internal carotid artery combined with roentgen irradiation may be considered the method of choice, while surgical removal of the tumor is indicated only in a few cases with particularly favourable location of the aneurysm.

Etiology of Myeloid Leukemia.—Kucharick reports 1 case of myeloid leukemia in a woman aged 37 who died seventeen days after the delivery of a full term infant girl whose weight was about 1,900 Gm. (4 pounds). The baby was emaciated but was normal from the hematologic point of view. It was concluded that either the placenta or the organism of the newborn had resisted the development of the disease, independently of whether one considers virus or neoplasm as the etiologic factor in leukemia. The author's case and similar cases in the literature clarify the problem of leukopoiesis so far as they suggest that any part played by the humoral leukopoietic substance may be excluded with regard to the pathogenesis of myeloid leukemia.

Biologic Introduction to Study of Agents Analogous to Yperite (Substances Called Nitrogen or Sulfur Mustard). L. Justin-Besançon, S. Lamotte-Barrillon and C. Polonovski.—p. 1511.
*Critical Study of Clinical Results Obtained at Time of Treatment of Forty Patients with Malignant Hemopathies by Administration of Nitrogen Mustard. L. Justin-Besançon, S. Lamotte-Barrillon and C. Polonovski.—p. 1518.
First Results of Biologic Research Obtained in Course of Therapeutic Study of Derivatives of Yperite. L. Justin-Besançon, S. Lamotte-Barrillon and C. Polonovski.—p. 1529.

Nitrogen Mustard for Treatment of Malignant Hemopathies.—Justin-Besançon and his co-workers treated 40 patients, 25 men and 15 women between the ages of 9 and 70 years, who had malignant hemopathies, with nitrogen mustard. Methyl-bis (β-chloroethyl) amine was administered by the intravenous route, a solution of 6 mg. of nitrogen mustard in 6 cc. of isotonic sodium chloride solution being used. One-tenth milligram per kilogram of body weight was injected daily in a single dose in the morning or in two fractional doses at twelve hour intervals. Smaller doses were employed in tired persons or children. The total dose of one course of treatment had never exceeded an average of 24 mg. per 60 Kg. of body weight. A second course of treatment at an interval of six to eight weeks was instituted in 5 patients with recurrences. The results demonstrated that nitrogen mustard can be considered a palliative only. There were important changes in the blood picture which differed from one patient to another. Repeated examination of the blood in the course of the treatment is required because of the risk of a toxic effect of the nitrogen mustard on the hemopoietic system. The leukocyte count decreased constantly for a week, and in rare cases for three weeks, to 2,000 to 3,000 in the absence of clinical symptoms. It then increased progressively within two or three weeks. The behavior of the red blood corpuscles was less uniform. In a number of cases the red cells showed a decrease parallel to that of the leukocytes. The anemia which was present before the initiation of the treatment subsided, suggesting that the bone marrow which was liberated from its pathologic elements was again able to assure normal erythropoiesis. Nitrogen mustard therapy should not be instituted earlier than at least two months after roentgen treatment has been terminated. Nineteen of the patients treated with nitrogen mustard had Hodgkin's disease. It is here that this agent is indicated, particularly in cases of roentgen-resistant disease, except for those in the terminal stage of the disease.

*Streptomycin in Tuberculous Meningitis. D. L. Gallo.—p. 1057.

Streptomycin in Tuberculous Meningitis.—Gallo reports 2 girls aged 16 and 26 years, respectively, with tuberculous meningitis. Streptomycin was given by intraspinal and intramucular injections. The younger patient received a total dose of 68 Gm. intrathecally and 78 Gm. intramuscularly. Clinical cure was attained which has persisted more than one year after discontinuation of treatment with streptomycin. There are no pulmonary lesions. The older patient received a total dose of 64 Gm. intramuscularly and 3 Gm. intrathecally. Definite improvement followed, which lasted for three months after discontinuation of streptomycin therapy. Acute symptoms including symptoms of involvement of the central nervous system appeared suddenly and terminated fatally. Necropsy revealed acute cerebral lesions. The author concludes that streptomycin is the only hope of cure for patients with tuberculous meningitis, the prognosis of which was fatal before discovery of streptomycin and is now slightly but favorably modified.

Book Notices

The Differential Diagnosis of Jaundice. By Leon Schiff, Ph.D., M.D., Associate Professor of Medicine, Department of Internal Medicine, University of Cincinnati Medical School, Cincinnati. Cloth. Price, $5.50. Pp. 313, with 39 illustrations. The Year Book Publishers, Inc., 301 S. Dearborn St., Chicago 4, 1946.

In this book, a discussion of the characteristics and classification of jaundice is followed by a presentation of the different diseases in which icterus occurs. Finally, an analysis is given of the clinical and laboratory aids helpful in the differential diagnosis of jaundice and also a detailed practical description for the performance of the commonly used hepatic tests. The latter includes a well illustrated and complete treatise on liver biopsy, one of the first in this country. The organization of the material is clear, and desired information is quickly found. The literature available at the time of the appearance of the book is thoroughly reviewed; nevertheless, the book makes for easy and interesting reading. In treating a subject such as the pathogenesis and diagnosis of jaundice, it cannot be avoided that some of the opinions given will be refuted by more recent experiences. The book clearly shows the great clinical experience and astuteness of the author and also good judgment in separating the important from less significant data. The book can be highly recommended for the practitioner because of its practical presentation and for the investigator because of the well chosen and rather complete references. It is one of the best expositions of this complicated and often discussed subject.

Medical Disorders of the Locomotor System Including the Rheumatic Diseases. By Ernest Fletcher, M.A., M.D., M.R.C.P., Physician to the Arthritis Clinic, Royal Free Hospital, London. Cloth. Price, $11. Pp. 625, with 263 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves, Baltimore 2, 1947.

This volume is almost entirely concerned with problems in the field of arthritis and other rheumatic disorders, although there are included chapters on "peripheral vascular disorders," one on "medical diseases of bone" and a chapter on "the foot." Also included are appendixes detailing data on solutions used for injections in and about joints, manipulations, epidural injections, serial plasters, optimum positions for ankylosis, technic for injections into joints and muscles, muscle-nerve testing and certain normal blood values. A major part of the volume was written by Fletcher, but several contributions of chapters on special subjects were prepared by other British writers.

The book is difficult to review, as the quality of material is exceedingly variable. Some is exceptionally good; for example, a chapter on applied anatomy of the locomotor system by G. A. G. Mitchell. A chapter on incidence and prevalence of rheumatism by Lewis-Faning reviews statistics for England and Wales but fails to mention important American and Scandinavian studies of recent years. The chapter on the treatment of rheumatoid arthritis is fragmentary and poorly balanced. Serious consideration is given to remedies long discarded as useless, including calcium iodoxybenzoate, neostigmine, colloidal sulfur, bee venom, sodium glycerophosphate. All are mentioned by the writer as having value. A section on gold therapy is included, but this is far from complete.

The subject of physical therapy in the treatment of rheumatoid arthritis is disposed of in 17 lines. Vaccine therapy for rheumatoid arthritis is given 20 lines; exercises are disposed of in a page and a half. High potency vitamin D therapy is given 2 pages without inclusion of the author's personal opinion of the value of this therapy. Treatment of Still's disease is completed in a paragraph of 6 lines.

A section on the treatment of osteoarthritis includes no mention of the use of physical therapy, although bizarre methods of therapy such as the injection of fat into joints and injections of lactic acid are treated seriously and without critical appraisal by the author. A chapter by Copeman on the subject of fibrositis presents the problem from an orthodox point of view but fails to tell the reader how this disease is to be recognized and how it may be distinguished from other forms of chronic rheumatism such as rheumatoid arthritis and osteoarthritis. The section on treatment of ankylosing spondylitis includes recommendations which, in this country at least, seem little short of amazing. The author suggests that treatment be conducted along "sanatorium lines and [that patients be] nursed on open air balconies." Opportunities to care for these cases in sanatoriums and on open air balconies are certaily not frequent in America where, excepting for unusually severe cases, most patients with spondylitis go about their business and carry on at fairly strenuous occupations while receiving treatment. The writer recommends, for spondylitis, "dairy products; plenty of first class protein . . . added vitamins are useful. . . ." In this manner the author often achieves an antique flavor in his writing but the result must be disappointing to the reader searching for a reasonable program for the treatment of these patients.

In his preface the author stresses the difficulties of preparing this volume and indicates his belief that he may have made many errors in its preparation. This suspicion appears to be justified after sober study of the book. In its present form it is not recommended as a practical reference work in this field.

Introduction to Health Education. By Jackson R. Sharman, Ph.D., Professor and Head of Department of Health Education and Physical Education, University of Alabama, Tuscaloosa. Cloth. Pp. 273. A. S. Barnes & Co., 67 W. 44th St., New York 18, 1948.

This volume is directed to school teachers, perhaps the most important group from which health education can be expected to come. The author points out that satisfactory progress in improvement of national health can come only if adequate health education is made available to children in the receptive years, before wrong ideas have been inculcated by haphazard, informal "education" on health. Sharman has made a significant contribution by providing excellent orientation for teachers and in giving specific methods for incorporation of health education into school curriculums. Due attention is given to the numerous points of contact with health education that are observed in every school or classroom operation. The author's style is conducive to easy reading. A helpful feature is a summary, a list of questions and a reference list after each chapter. This book can provide important impetus to rapid progress of health education in schools. It is recommended to teachers who are coming to grips for the first time with how to introduce health education. It is equally valuable for teachers already in this field, because of the compactness and completeness with which it reviews the subject.

Modern Trends in Ophthalmology. .Volume II. Edited by Arnold Sorsby. Second edition. Cloth. Price, $12.50. Pp. 600, with 169 illustrations. *Paul B. Hoeber, Inc.*, 49 E. 33rd. St., New York 16, 1947.

Volume I was published in 1940 in an attempt to fill the gap between the systematized knowledge found in textbooks and the ferment found in the periodic literature. In advance of one and lagging behind the other, its ill defined position shows considerable local color, so that even in the modern world there are tangible distinctions between the teaching and practice of different countries and different clinics. Contributors have been sought in three continents, and the various contributions deal, not with textbook material, but with the as yet unsystematized knowledge that is emerging from clinics, laboratories and the periodic literature. The contents of the book emphasize neither that which is already established, nor that which is as yet unformed, but indicate the emergent tendencies and formative influences. An attempt has been made to fill the many gaps in the preceding volume and to indicate the considerable developments that have occurred during the past seven years. The bibliographies are selective and are intended to serve as guides to the literature and not as exhaustive lists of references.

Section one on physiology contains 10 chapters of which two articles on electrophysiology of the retina and senescence of the eye contain considerable new knowledge not found in textbooks.

Section two contains 4 chapters on diagnostic procedures, devoted mostly to slit lamp and gonioscopic studies.

Section three, with 16 chapters on pathology, introduces some excellent material on virus affections, retinal vein changes and visual disturbances in glaucoma.

The fourth section, on treatment, contains interesting subject matter on sulfonamide and penicillin therapy, contact lens, trends in cataract surgery and the handling of burns with amniotic membrane grafts.

Section five consists of four articles on social aspects, pertaining especially to aviation medicine and the care of the blind in England and Wales.

The subject matter is written for the mature practicing ophthalmologist and will be found to be worth while reading, especially for those not conversant with the present literature.

Protomorphology: The Principles of Cell Auto-Regulation. By Royal Lee and William A. Hanson. With an appended article on "Cytotoxines;" by Prof. K. R. Victorov. Cloth. Price, $8.50. Pp. 365, with 9 illustrations. Lee Foundation for Nutritional Research, 2023 W. Wisconsin Ave., Milwaukee 3, 1947.

In the author's words: "We shall review evidence which has led us to suggest the hypothesis that the genes contain an organized assemblage of smaller units which are the determinants of individual cell morphology. For these units we propose the name 'cytomorphogen.' . . . We propose that a cytomorphogen is composed in part of still simpler and quite stable units composed principally of minerals which are the determinants for the specificity of the biologic proteins. For these basic determinants we propose the name 'protomorphogen.' We define a protomorphogen as a comparatively stable but complex group of molecules, linked together by the chemical affinities of mineral matter, which by reason of its physical and chemical structure determines the exact plan or pattern by which the component parts of a specific protein are combined."

This mineral " 'skeleton' of the complicated protein molecule" is supposed to retain its structural integrity and specificity after ashing of tissue at 300 C. and resolution to give a 10 per cent saline solution of the resulting ash. This saline solution on injection intravenously into the species of animal from which it is derived may result in shock and death in five seconds to two minutes. The hypothetic mineral protomorphogen solution is postulated to serve "as a framework upon which organic components are assembled into an antigenically active foreign protein. The serologic reaction therefore is against this protein and not directly against the ash itself."

The contradiction between these hypotheses and elementary and well established facts of chemistry on the one hand and of immunology on the other hardly need be pointed out to the informed reader. To follow their further discussion and elaboration would not serve a useful purpose. The authors have read widely, but uncritically, and the considerable body of information derivable from the literature cited seems to have undergone serious distortion through being forcibly related to the basic hypotheses as frame of reference. The reviewer fails to find justification for the book or for the experimental pursuit of the specific hypotheses proposed therein.

Index of Diagnosis (Clinical and Radiological) for the Canine and Feline Surgeon. By Hamilton Kirk, M.R.C.V.S. Third edition. Cloth. Price, $10. Pp. 600, with 321 illustrations. William Wood & Co., Mt. Royal & Guilford Ave., Baltimore 2, 1947.

The author is official veterinary surgeon to the Clayton Greyhound Stadium. His experience, that of Dr. Gerry B. Schnelle of the Angell Memorial Hospital in Boston and of others have been drawn on to help make the first two editions of the "Index of Diagnosis" popular with small animal practitioners.

The third edition of "The Index of Diagnosis" is improved by deletion of many references to treatment that appeared in the first two editions. Several new articles have been added, including Schlatter's disease, pneumothorax, epulis, pathologic fractures, osteogenesis imperfecta, kyphosis, lordosis, pigmentation, hernia, hydrops amnii, dental decay, extrauterine pregnancy, sunstroke, heatstroke and bone tumors. A number of new drugs have been added to the extended section on poisoning. The attempt to differentiate between Stuttgart disease and black tongue is still not convincing.

It is proper that the major advances in the medical sciences should be aimed at the alleviation of suffering of human beings. Most of those advances are based on work done on experimental animals, including the dog and cat. It would seem a simple task to utilize the advances gained for medicine through use of the dog and cat for the benefit of those animals. Actually the task is not simple, and whereas the dog and cat have benefited greatly from work done with them for the benefit of human beings, much of the information gained through work on the dog and cat is not realized for the benefit of those animals.

It is gratifying to note the several references to the work done on animals in medical laboratories. The most potent answer to antivivisection "forces" is the relief of suffering to dogs and cats that has been contributed by research work in medical laboratories. Indeed, the lack of reference to other important work is the chief criticism of the book. The Habel mouse test for rabies is not mentioned. The information on the prostate gland is outdated. The information on vomiting is erroneous. The author overlooked all the evidence, beginning with Magendie in 1813, that vomiting is purely a reflex phenomenon. And for species differences in vomiting he might look more fruitfully to the cardiac end of the stomach rather than the pyloric. Fox or "Fox encephalitis of dogs" is not mentioned as a disease entity.

This book is a valuable addition to the library of any veterinarian or research worker who works with dogs and/or cats.

The Skull, Sinuses and Mastoids: A Handbook of Roentgen Diagnosis By Barton R. Young, M.D., Professor of Radiology, Temple University Medical School, Philadelphia. Cloth. Price, $6.50. Pp. 328, with 141 plates. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1948.

This book present a brief but complete outline and discussion of roentgen diagnosis of the head. The arrangement of the material is somewhat unusual; on one page is presented a discussion of a particular subject, and on the opposite page is a clear reproduction of a roentgenogram, fully indexed, illustrating the points discussed. The subject of roentgenography of the head appears to be well covered.

This handbook should serve as an excellent reference book for roentgenologists and those doing only a limited amount of diagnostic work on the head. It should find a place on the shelf of every physician who attempts a diagnosis of lesions of the skull, sinuses and intracranial contents.

The reproductions are of good quality and readily understood. The concise manner of presentation and the brevity of the text recommend it.

Thromboendangiitis obliterans des Gehirns: Neurologisch-psychiatrische Syndrome. Von F. Llavero. Cloth. Price, 24 Swiss francs. Pp. 248, with 15 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Benno Schwabe & Co., Klosterberg 27, Basel 10, 1948.

In general thromboangiitis obliterans has been considered as a disease of the extremities. Only in recent years has it been appreciated that a similar disease process may affect the cerebral vascular system. Even now this fact is not commonly recognized. This monograph is devoted to a detailed presentation and clarification of this problem. Its more important sections deal with the pathologic anatomy and the etiology; the presentation of a series of 14 cases and the analysis of the clinical picture; a discussion of the accessory diagnostic methods such as encephalography, arteriography and capillary microscopy; the examination of the fundus oculi and the spinal fluid; the differential diagnosis; the prognosis and treatment. There is an extensive bibliography, but no index.

Neutron Effects on Animals. By the Staff of the Biochemical Research Foundation. Dr. Ellice McDonald, Director, Newark, Delaware. Cloth. Price, $3. Pp. 198, with illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves, Baltimore 2, 1947.

The staff of the Biochemical Research Foundation have recorded, in a series of articles written by various members, the results of eight years' work concerning the effects of neutron bombardment in animals. This work was done with a cyclotron built especially for biologic research and under the direction of Dr. Ellice McDonald, director of the foundation. Certain projects included in this study were done at the request of the Manhattan District. In general, the various papers present the details of changes in cellular activities following neutron bombardment. The usual laboratory animals and the accepted criteria of radiation effect were utilized. The material is presented in a clear and concise manner and should be of value to those interested in the effects of neutron bombardment.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

DIET IN ULCERATIVE COLITIS

To the Editor:—Please send the list of the dietary treatment in ulcerative colitis in the early stages. What is the present opinion of the effect of tobacco and alcohol on the condition? Is medicinal therapy indicated in these stages, and if so, what dosages of the drugs are indicated?

Matthew A. Mroz, M.D., DeLand, Fla.

Answer.—The following dietary program has served well. The activity of the disease will determine the phase of the diet on which a patient is placed.

Approximate composition of this diet (actually a variation of 10 per cent in the composition of the diet is assumed):

	Unit.	Foundation Diet	Full Diet
Carbohydrates	Gm.	195	270
Protein	Gm.	85	145
Fat	Gm.	125	215
Calories	....	2,210	3,600
Calcium	Mg.	470	1,940
Iron	Mg.	11	17
Vitamin A	I.U.	4,300	7,800
Thiamine	Mg.	1.1	2.5
Riboflavin	Mg.	1.5	4.0
Nicotinic acid	Mg.	14	18
Ascorbic acid	Mg.	25	105

The initial or foundation diet is served to patients with chronic ulcerative colitis. At the outset of a well ordered program, it is a diet low in residue. Additions of food are made as tolerated so as to increase the calories and protein as quickly as possible. One additional food as well as increased size of servings is given each day unless otherwise ordered by the physician. Protein concentrates may be used or nonfat milk solids may be added to fruit juices or milk as suggested here. In general the use of tobacco and alcohol is contraindicated in patients with active ulcerative colitis. The question of medicinal therapy is difficult to answer because new drugs are constantly coming into use. Among the sulfonamide compounds the most satisfactory ones have been phthalylsulfathiazole, 15 to 22½ grains (1 to 1.53 Gm.) every three hours, or azosulfamide ("neoprontosil"), 10 to 15 grains (0.6 to 1 Gm.) every three hours. These drugs can be given for approximately two weeks at a time for the average patient, and after a rest of a week or so they may be resumed for a similar period of two weeks. Innumerable other drugs are being used, and these will be found in current publications.

HEART BLOCK

To the Editor:—A patient with heart block has heart beats thirty-six to forty-two times per minute, and shortening of breath. The attack came on rather suddenly and has not required oxygen. Please advise treatment.

W. H. Bollinger, M.D., Charleston, Ark.

Answer.—It is important to make a differential diagnosis of the cause of the auriculoventricular block since treatment of certain underlying conditions may greatly benefit the heart block, and also important to ascertain whether the block is complete or incomplete. On the assumption that the heart block is complete because of the slow ventricular rate, ordinarily no treatment is necessary. If there are untoward symptoms due to the slow ventricular rate, therapy aimed at accelerating the rate may benefit the patient. Thus ephedrine sulfate, ¼ to ½ grain (15 to 30 mg.) three to six times daily, or "paredrine hydrobromide" (1-[para-hydroxyphenyl]-2-aminopropane hydrobromide), 20 to 40 mg. three times a day, may be given. This is especially true if Adams-Stokes attacks occur. In such instances epinephrine in oil, 1 cc. once or twice daily, may be most useful.

The dyspnea present in this patient may be due to congestive heart failure. If the heart block is complete, full digitalization may be accomplished, since the block cannot be made worse. The dyspnea may be alleviated and the heart block may even disappear on the return to a state of compensation.

"AGENIZED" FLOUR

To the Editor:—I recently read an article on the use of nitrogen trichloride ("agene" gas) in the milling and bleaching of white flour. The inference was that consumption of bread made from this flour is injurious to human beings. Any information in regard to this subject would be appreciated.

M.D., Canada.

Answer.—"Agenized" flour is a product which is produced by exposing the flour to nitrogen trichloride gas ("agene"). "Agene" was widely used in the United States for improving the baking quality of flour until recently.

In 1946, Mellanby in England reported the production of "canine hysteria" (running fits) by feeding dogs flour treated with nitrogen trichloride ("agene") and proved that the toxic element was developed in the process by the action of the nitrogen trichloride on the wheat protein. American investigators have confirmed his findings.

In all these studies the level of "agenized" flour necessary to produce a reaction in dogs is substantially higher than the level of flour which would be used in an ordinary human diet.

Dr. Elvehjem reported that experiments on 12 human beings have revealed no symptoms or encephalographic changes after eating "agenized" flour or "agenized" gluten in amounts which would unfailingly produce hysteria in dogs (J. A. M. A. **135**: 760-763, 1947).

The Food and Nutrition Board of the National Research Council stated that it feels that the use of "agene" in treating flour should be abandoned in the shortest time which is economically feasible. A more complete discussion can be found in the Nov. 22, 1947 issue of The Journal.

HOOKWORM

To the Editor:—In rural North Carolina I have seen a number of cases of young adults and children with symptoms of acute appendicitis and a history of previous similar attacks. Examination usually reveals decided tenderness over the appendix, but no rebound, rigidity or fever, a normal temperature, secondary anemia and a stool loaded with hookworm ova. I have treated these cases of hookworm conservatively. So far my results have been good. Is a diagnosis of appendicitis due to hookworm correct here? Am I justified in treating these cases conservatively? How much danger is there of rupturing the appendix with the saline purgative which follows the use of tetrachloroethylene, assuming my diagnosis is correct?

M.D., North Carolina.

Answer.—You are quite right in considering appendicitis in your differential diagnosis; however, the adult worms inhabit the small intestine and especially the middle portion, where they feed on the mucous membrane. It is generally considered that about 100 worms are necessary to produce symptoms in an average person. The predominant complaints are lassitude, fatigue, anorexia, distention and anemia. The finding of ova in the stool is definite evidence of clinical disease. Against the diagnosis of acute appendicitis is the absence of rebound pain and the presence of a normal temperature, slight or no leukocytosis, with eosinophilia in the neighborhood of 20 to 40 per cent.

The only parasites which may be found in the terminal part of the ileum and in the appendix are the whipworm (Trichuris trichiura) and the pinworm (Enterobius vermicularis), and, although they may rarely cause a fulminating type of appendicitis, they usually are associated with a more chronic form known as "wriggling appendix."

The danger of rupture of the appendix with saline purgative is virtually nil.

HYPERTENSION AND ALTITUDE

To the Editor:—Is it considered inadvisable for a person with hypertension to spend a vacation at high altitude?

M.D., New York.

Answer.—The advisability of residence at high altitudes for patients with arterial hypertension is conditioned by several variables: (1) the severity of the hypertension, including the extent of permanent arteriolarsclerotic change; (2) the age of the patient; (3) the hemoglobin content of the blood; (4) the elevation of the area; (5) the amount of physical activity to be indulged in, and (6) the rapidity of ascent. In general, it may be said that it is unwise for the hypertensive person to go to altitudes in excess of 6,000 feet if he is not accumstomed to such levels and intends to be physically active. Anoxemia is exaggerated greatly by even relatively minor degrees of anemia, and thus myocardial histanoxia is a potential hazard. Each problem should be evaluated individually; generalizations are misleading, especially when so many variables affect the prognosis.

DRUGS AND STERILITY

To the Editor:—I am treating a veteran who suffered from seizures following gunshot wounds in the head. The patient has a tantalum plate in the skull. Before beginning of treatment he suffered frequent epileptiform seizures. He was put on diphenylhydantoin sodium and trimethadione, and soon these seizures stopped. He has had no seizures for many months. For about a year he has been kept on two 1½ grain (0.1 Gm.) capsules of diphenylhydantoin sodium and one 5 grain (0.3 Gm.) capsule of trimethadione, which keeps him seizure free. He and his wife are in the middle twenties, have been married about three years and desire a child. He was examined by an eminent urologist, who told him that *while his seminal fluid contained live and active spermatozoa, they* were deficient in numbers. He was told to ask me whether the continued taking of diphenylhydantoin sodium or trimethadione would interfere with the production of the spermatozoa. I was unable to answer this question. What influence has continual medication with diphenylhydantoin sodium or trimethadione on the production of the spermatozoa?

James Watson, M.D., Lakewood, Ohio.

Answer.—According to the literature no clinical investigations have been done concerning the effect of diphenylhydantoin sodium or trimethadione on spermatogenesis. It would be well to get another seminal fluid analysis with an accurate count of the spermatozoa in the seminal fluid. It is definitely known that certain drugs, especially sex hormones, do interfere with the production of spermatozoa when used over a long period of time.

PSYCHOGENIC IMPOTENCY

To the Editor:—A man aged 43 complains of impotency lasting about ten years. He was married six years ago hoping to improve. He performs vulvar intercourse with orgasm but his wife is still virgin. The urologist says that he has no genital abnormalities, and treatment has failed with several hormones. The genitals are rather small. Psychoneurotic symptoms and neurologic abnormalities are absent. The patient has a stormy genital history, including unilateral orchitis and ulcer. He had a traumatic penile lesion in childhood and gonorrhea following the first intercourse. He had a strict moral education and has strong feeling of guilt. Before the present condition he avoided sexual activities for several months for religious reasons, and he did have a transient episode of impotence. He shows no other personality difficulties. Please suggest probable cause and most satisfactory approach to this case.

Vandick Ponte, M.D., Fortaleza-Ceará, Brazil.

Answer.—It would appear from the history that this patient's sexual troubles are on a psychogenic basis, especially since the urologist that examined him can find no evidence of genital abnormalities. On the other hand, if he has bilateral testicular atrophy, it could be that his symptoms are due to a deficiency of male sex hormone. If such is the case then intramuscular injection of testosterone propionate three times a week might be indicated. This treatment might be tried for six weeks to see whether the patient derives any benefit. If not, it should be discontinued, and the patient examined by a good psychiatrist. His wife should consult a gynecologist and have her hymen incised.

VITAMIN D DOSAGE

To the Editor:—Is 5 mg. of vitamin D excessive for patients past middle life? This seems to be about the contents of the tablets of mixed vitamins for patients who are on a restricted diet for maintenance.

M.D., Maine.

Answer.—Five milligrams (about 200,000 U. S. P. units) of vitamin D is an excessive dose for any patient except perhaps in very special circumstances. For adults the optimal amount of vitamin D, if a need exists, remains to be determined. For adults who have no opportunity for exposure to clear sunshine and for elderly persons, the ingestion of small amounts of vitamin D may be desirable. The normal requirement probably does not exceed 400 U. S. P. units of vitamin D daily and may be less.

LIVER EXTRACT IN CIRRHOSIS

To the Editor:—What is the usual duration of intravenous treatment with liver extract in hepatic cirrhosis? How long should it be continued after the patient's condition seems to have remained unimproved?

G. Bruce Lemmon Jr., M.D., Springfield, Mo.

Answer.—The only large experience with the intravenous use of liver extract in the treatment of cirrhosis has been recorded by investigators from the Rockefeller Institute (Labby, D. H.; Shank, R. E.; Kunkel, H. G., and Hoagland, C. L.: Intravenous Therapy of Cirrhosis of the Liver. J. A. M. A. **133**:1181-1190 [April 19] 1947). They found that the material used increased appetite and the intake of food, produced changes indicating improvement in various tests of hepatic function and caused a disappearance of ascites in 12 of 21 cases, with reduction in the rate of formation of ascites in 7 more cases in the same group. Even more impressive are their figures for survival; 77 per cent of the group of patients studied have survived for two years or more. Labby and his co-workers pointed out that at least a six months' trial of therapy is required to evaluate the effects of this type of treatment in so chronic and well established a disease as cirrhosis. They also have cited a case in which slight improvement was noted at the end of five months of treatment but in which formation of ascites did not cease until after thirteen additional months of treatment. It would appear from their figures that at least six months' treatment is essential for a fair trial and that under certain circumstances it may profitably be continued for a much longer period of time.

CONGENITAL DEFECT OF HAND

To the Editor:—A newborn son has a congenital defect of the right hand consisting of a webbing between the first three fingers. The webbing is palm thick at the base of the fingers and narrows down to a membrane at the proxmial interphalangeal joints. The two distal phalanges of these three fingers are about half normal size. The entire hand is somewhat smaller than the left one. My questions are these: 1. When had I best attempt surgical treatment? 2. Could I increase the size of the right hand by assiduous applications of heat over a period of years?

C. S. Dorsey, M.D., Kingston, W. Va.

Answer.—1. Generally speaking, reconstructive operations on congenital defects of the type described ordinarily are carried out somewhere between the ages of 5 and 8 years. The problem, however, must be individualized, and occasionally earlier operation might be indicated, although the procedures are usually executed with greater ease when the hand is more fully developed.

2. It is highly improbable that application of heat or any other local therapy would be of any benefit.

BACTERIOSTATIC OILS

To the Editor:—Are there any food-preserving qualities in such condiments as mustard, horseradish, and various types of peppers?

Duncan C. McKeever, M.D., Houston, Tex.

Answer.—The volatile oils found in various condiments or spices do possess bacteriostatic properties. The resistance of micro-organisms to the action of spices varies with the organism and with the spice. The decreasing order of the germicidal activity of the spice components is reported as follows: allyl isothiocyanate (mustard, horseradish) and carvacrol (caraway seeds) (equal); cinnamicaldehyde and cinnamyl acetate (cinnamon) (equal); eugenol (cinnamon, cloves); eugenol methyl ether (cinnamon, cloves), and eucalyptol (*Chem. Abstr.* **38**:4638 [Sept. 10] 1944).

The chemical constituents of pepper oils are still little known (Osol, A., and Farrar, G. E.: United States Dispensatory, ed. 24, Philadelphia, J. B. Lippincott Co., 1947) and no statements as to their bacteriostatic properties can be found, although it is quite possible that they do possess such bacteriostatic properties. No instances are known where spices are relied on as the sole preservative of foods.

SILICA HAZARD

To the Editor:—In the brewing industry, diatomaceous earth or kieselguhr is used as a filtering medium. Is there any occupational hazard in handling the powder?

M.D., Massachusetts.

Answer:—The content of silica in diatomaceous earth is in excess of 80 per cent. The greater portion of this content represents free silica, the source of silicosis. Much of diatomaceous earth is of fine particle size and within the range capable of entry into the lungs. Provided sufficient concentration and over long periods of time, silicosis from diatomaceous earth is a possibility. On a practical basis the brewery situation, as to silicosis, depends on the regularity of exposure, the concentration and the duration in years. Intermittent operation such as involving only a few minutes and in such intervals as three or four times weekly will introduce no prospect of silicosis. Exposed workers, even on irregular work, should be provided respirators. If the operation be continual, dust counts should be carried out to determine concentration level.

VENOUS BLOOD CELL COUNT

To the Editor:—Is it satisfactory to use venous blood for the determination of red cell count, white cell count and hemoglobin? I should like to use the same blood for chemical studies and for these tests if satisfactory.

M.D., New York.

Answer.—Use of venous blood for red cell count, white cell count and hemoglobin determination is perfectly valid.

CLINICAL USE OF BLOOD DERIVATIVES

CHARLES A. JANEWAY, M.D.
Boston

Physiologic reasoning underlies sound practice in all fields of medicine today. But physiology, in turn, is dependent on chemistry for insight into the fundamental nature of the phenomena of health and disease. The work of a distinguished company of clinicians and medical scientists over a long period of years has evolved our present state of knowledge of the multiple functions of the blood and of their dependence on the molecular properties of the specific proteins by which they are mediated.

The development of blood derivatives stems logically from this concept that each function of the blood is due to one or more specific components. Great progress has been made in the decade since plasma first came into general clinical use as a derivative of blood in which its osmotic and certain of its nutritional properties could be preserved for use when separated from the more labile cells. Chemical and physical advances have led to better preservation of the cellular components and to the introduction of large scale methods for the separation and purification of plasma proteins for clinical use. These developments not only have yielded important therapeutic results but have given investigators new tools with which to obtain a more thorough understanding of human physiology and its derangements in disease. For example, a β_1-globulin, which has been crystallized from fraction IV-7 of human plasma,[2] accounts for the capacity of the plasma to bind and transport iron.[3] Isolated in pure form, it has been possible to study the reactions of this protein with iron in the laboratory and to make parallel observations on patients.[4] From these investigations has come new insight into iron metabolism and transport, although no disease has yet been found in which a deficiency of this metal-binding globulin requires replacement.

In discussing the clinical use of blood derivatives, it is important to reemphasize the difference between stimulation and replacement therapy. In the former, the patient is stimulated to replenish his own deficit (e. g., the treatment of hypochromic anemia with iron salts) while in the latter, the deficiency is made up by passive transfer from a donor. This has the advantage of immediate rectification of the deficiency, but the effect is relatively short lived and does not reach the fundamental cause. Blood derivatives are indicated for the replacement therapy of specific deficiencies of the blood, whenever speed is important or stimulation therapy is not effective or not available.

Figure 1 clearly indicates the gross differences in composition between certain available derivatives, and the reason that their use for specific indications leads to greater therapeutic effectiveness. Since the recruitment of donors is the most difficult practical task in any blood program, the economy in the use of blood made possible by its separation into fractions, in each of which one or another specific function is concentrated, is of considerable importance. The extent to which the usefulness of a single donation of blood can be magnified by fractionation is seldom appreciated. Table 1 shows what can be derived from the fractionation of twenty blood donations. A glance at the column marked "Dating Period" brings out another important consideration. Many of the important blood components are labile and undergo rapid deterioration in whole blood. Separated and concentrated, each may be packaged in a state best adapted to the preservation of its functional activity, ready for clinical use whenever and wherever it is needed.

BLOOD CELLS

The cellular components of the blood deserve further chemical study. Satisfactory methods for concentration and preservation of the unstable granulocytes and platelets do not exist. Because the red cells contain the most important blood protein, hemoglobin, which is responsible for the vital function of oxygen transport, considerable effort has been expended in improving methods for their preservation. At present, cells taken

From the Department of Pediatrics, Harvard Medical School and the Children's Medical Center, Boston.

Read in the General Scientific Meetings at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 22, 1948.

This paper is number 74 in the series "Studies on the Plasma Proteins" from the Harvard Medical School, Boston, on products developed by the Department of Physical Chemistry from blood collected by the American Red Cross.

This work was originally supported by grants from the Rockefeller Foundation and from funds of Harvard University. It was aided early in 1941 by grants from the Committee on Medicine of the National Research Council, which included a grant from the American College of Physicians. From August 1941 to July 1946, it was carried out under contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Harvard University. Since then it has been aided by a grant, recommended by the Panel of Hematology of the National Institute of Health, from the United States Public Health Service.

into chilled bottles containing some modification of the ACD formula and allowed to sediment at 4 C. will keep about as well with most of the plasma removed as they would if kept as whole blood.[5] The amounts of hemoglobin relative to plasma protein and sodium in whole blood and in red cell suspensions shown in figure 1 apply to the Children's Medical Center, where a modified ACD solution, 70 cc. to 500 cc. of blood, is used. After sedimenting in the cold overnight and withdrawal of the supernatant plasma, the cells may be resuspended by shaking, and the suspension, which has a hematocrit reading of approximately 65 per cent, can be used without dilution.[6] Cell suspensions require filtration through gauze or wire mesh and must be mixed with slightly hypertonic sodium chloride solution (1 per cent) if a diluent is used. Red cell suspensions have two great advantages in the treatment of patients with anemia of all types except those due to acute blood loss or severe infection, where there may be a deficit of plasma protein as well. First, they supply more hemoglobin with less of the osmotic activity of the plasma proteins and with less sodium, thus increasing the dose that can be safely given without overloading the circulation. Second, while they provide material for replacement of hemoglobin deficits, the plasma which the patient does not need is saved for other uses. The effectiveness of red cell suspensions was clearly demonstrated[7] even before the substitution, for sodium citrate solution in which 70 per cent of the cells remain viable for only seven to ten days, of ACD solution in which 70 per cent viability can be extended to at least twenty-one days.[8] An important consideration in the use of cell suspensions is the demonstration by the radioactive-iron technic that the iron of the nonviable cells can be efficiently reutilized for hemoglobin synthesis.[9] More work needs to be done in extending the period of life of the red cell in vitro and in the development of practical methods for the general distribution and clinical use of red cell suspensions.

TABLE 1.—*Effect of Fractionation on Utilization of Twenty Blood Donations*

Derivative	Dating Period	Clinical Use	No. Packages	No. Patients Treated	Total
Whole blood........	21 days	Hemorrhage	20	20	20
		Separation of Cells and Plasma			
Red cells............	21 days	Anemia	20	20	30
Dried plasma........	5 yr.	Shock, hypoproteinemia	10	10	
		Fractionation of Blood

Fraction I...........	1 yr.	Hemophilia, surgery	30*	30	
Gamma globulin.....	3 yr.	Prophylaxis of infections	80	80	
Serum albumin......	5 yr.	Shock, hypoproteinemia	5	5	
Isohemagglutinins†..	1 yr.	Blood grouping	100	2,000	2,150
Thrombin †..........	1 yr.	Hemostasis	150	150	
Other fractions......	.....	Further research	...	...	...

* Alternatives: fibrin foam or fibrin film.

† Yield of these products is so large that they need be produced only from occasional runs.

The processes of chemical fractionation have been applied to the red cell as well as to the plasma. Methods for the preparation of hemoglobin in a relatively stable state have led to investigations of its physiologic activity in solution.[10] Hemoglobin solutions combine oxygen-carrying power with high osmotic activity (the molecular weight of hemoglobin is about the same as that of serum albumin, although it can split into two half-molecules) and therefore act dramatically in experimental shock. Although a few preliminary studies on the use of hemoglobin in shock in human beings have been made, the fact that renal function is temporarily depressed when it is given to experimental animals has properly made all investigators cautious about its clinical use.[11] It is not by accident that nature has chosen to surround hemoglobin at a concentration of 30 per cent with the semipermeable membrane of the erythrocyte. A derivative of hemoglobin, modified globin, has been developed to act as a plasma protein substitute.[12] Further work will be needed before its place in therapy can be finally evaluated. Globin offers the possibility of salvaging the large amount of protein in outdated red cells for nutritional use. The considerable number of active enzymes—catalase, hypertensinase, choline esterase and others—found in the erythrocyte should stimulate further work on their purification from this important human source.

PLASMA

The value of plasma as an emergency blood substitute in the treatment of shock due to blood loss is too well known for further comment. As Evans has indicated, plasma and albumin are substitutes for blood, providing colloid osmotic activity, salts and water which will replace the blood lost and restore the circulation, but lacking the oxygen carrying power of hemoglobin. Thus the plasma-treated or albumin-treated shock patient may recover from his shock, but will then be an anemic patient,[13] with tachycardia, diminished tolerance to exercise and possibly a slower rate of healing. However, the most serious difficulty with plasma has arisen from the practice of pooling and from the excellence of the method of drying from the frozen state used to preserve its labile components, both of which, combined with the stability of the virus, have led to the spread of homologous serum jaundice by means of pooled dried plasma. Table 2, which gives the best available statistics, indicates the relationship of the incidence of serum hepatitis to the size of the pool. The statistics for this country have been gathered through studies initiated by the American Red Cross as part of its blood program. Although no cases were observed after blood or single serum transfusions in the series reported, the disease has been recorded in scattered patients who have received only whole blood transfusions.[14] The statistics for the plasma fractionation products are incomplete, but with the very large pools used, the expected incidence would be very high, while in actual fact it has been negligible, except with fraction I.

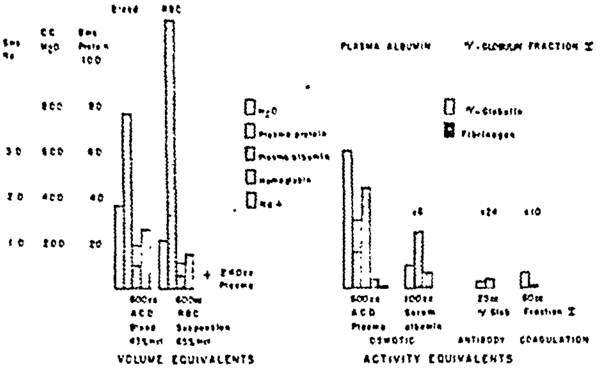

Fig. 1.—Comparison of composition of blood and certain derivatives with respect to water and sodium and their major protein components.

The control of this disease is one of the most important practical problems in medicine. Three approaches are possible; first, development of better screening methods for infectious donors; second, development of methods of immunization against the disease, and, third, development of methods for the sterilization of blood and plasma. Work on all three lines is in progress, but the third approach seems most promising. Although proof has not yet been obtained that ultraviolet irradiation, which acts by its effect on certain proteins, will inactivate known hepatitis virus in large scale processing without altering the labile proteins chemically, there is sufficient evidence of its effectiveness to be optimistic.[15] Passive immunization with human gamma globulin has yielded equivocal results and hardly seems practicable except for the recipients of a pool found to be infected.[16] At the present time, pooled plasma should be used only for clear indications when neither blood nor serum albumin are available .

PLASMA FRACTIONS

The development of large scale methods for the concentration of the protein components of human plasma into fractions, from which various derivatives can be prepared in the form best adapted to preserve their physiologic activity for therapeutic use, has had an important impact on many phases of medicine.[17] These methods, designed for the separation of specific proteins from mixtures, have been applied to the purification of virus vaccines, toxoids, animal serums and tissue extracts, as well as plasma. Although introduced for the separation of half of the plasma protein, serum albumin, from the remaining less stable globulins, so as to provide a compact stable blood substitute during the war, the methods are inclusive, so that a single fractionation process yields all the major components of plasma with minimal losses and minimal denaturation of the labile components. During the Army-Navy-Red Cross blood program of the war, slightly more than two million blood donations were subjected to fractionation, yielding products which were used by the armed forces, returned to the American people when surplus and used in part for research. Since the war, the Red Cross has continued the distribution of surplus blood derivatives—plasma and the products of plasma fractionation—for therapeutic use when the supply has been adequate and the value proved, or for clinical investigation in other instances. Small amounts are also available from one commercial source. The following brief résumé of the present status of the plasma fractionation products is based on published data, personal experience and the work of many investigators who have cooperated in recent studies, for which blood derivatives have been provided by the National Blood Program of the American Red Cross.

Table 2.—*Homologous Serum Jaundice*

1. *Products of Proteins Involved in Coagulation.*—The value of fibrin foam with thrombin as a hemostatic in many types of surgical procedure is well documented.[18] Whether the foam can be completely supplanted by "gelfoam" (absorbable gelatin sponge)[19] prepared from gelatin or by oxidized cellulose[20] is a problem which only time can solve. Whether potentially antigenic thrombin from animal sources should be used instead of human thrombin, which can be obtained in large amounts in any fractionation program, is a different problem. In any case fibrin foam with thrombin is one of a group of three types of absorbable hemostatic sponges, all of them effective, now available to surgeons in this country. Fibrin film, which has proved so valuable as a dural substitute in neurosurgery,[21] is being compared with film prepared from the plastic polyethylene.[22] Fibrinogen, which forms the matrix of the clot and constitutes 65 per cent of the protein of fraction I, has been used both topically and parenterally. Besides its use with thrombin as a means of attaching skin grafts,[23] it has been employed for the removal of renal stones in an ingenious procedure, whereby a solution of fibrinogen injected into the renal pelvis is coagulated with thrombin and the resulting clot drawn out with all its entrapped calculi.[24] Fraction I has been given in large amounts to several patients, whose blood totally lacked fibrinogen and who were suffering serious bleeding in consequence.[25] Here are instances in which, because of its low concentration in the plasma, it is impossible to give enough fibrinogen by whole blood or plasma transfusion, whereas with fraction I it has been possible to administer a dose equivalent to the total normal circulating fibrinogen.

Table 3.—*Summary of Results with Normal Serum Gamma Globulin in Common Diseases* *

Disease	Immunity in Infancy Early	Value of Globulin	
		Prevention	Treatment
Measles	+	+	±
Infectious hepatitis	—	+	0
Mumps	+	0	0
Scarlet fever	+	S	S
Poliomyelitis	+	—	0
German measles	+	S	—
Chickenpox	0	0	—
Infantile diarrhea	0	0	0
Homologous serum jaundice	—	S	—

Key: + Effective; ± questionable; 0 ineffective; — not known, and S under study.

* Reprinted from Cohn, E. J.: History of Plasma Fractionation, in Andrus, E. C.: Advances in Military Medicine, Vol. 1, Boston, Little, Brown & Co., 1948.

Fraction I, although mainly composed of fibrinogen, also contains other proteins, including the substance which will rectify the coagulation defect in hemophilia; hence the term "antihemophilic globulin." Two hundred to six hundred milligrams of fraction I, reconstituted in 5 to 30 cc. of sterile water and given intravenously, will temporarily shorten the coagulation time in hemophilia in the same way as fresh blood or plasma.[26] Although this product has been proved effective for the temporary control of bleeding episodes and for preparation of patients for dental and surgical procedures, material of high potency can be prepared only from fresh plasma, because of the lability of this protein. Dosage figures will mean little until fresh plasma can be used as starting material and methods of assay can be better standardized.

2. *Blood Grouping Globulins.*—The anti-A and anti-B agglutinins as well as the anti-Rh agglutinins are globulins and can be concentrated as part of the fractionation procedure to yield blood grouping reagents of high potency; provided that the plasma pool from which they are prepared consists of plasma of a single type.[27] The need for readily available accurately standardized potent reagents for the vital blood grouping tests is fundamental to any blood program.

3. *Antibodies.*—The value of the gamma globulin fraction (fraction II) in the prevention and modification of measles was demonstrated in 1943 and 1944.[28] Since that time the use of gamma globulin for this purpose has become standard public health practice in this country. The extent to which a blood program will be called on to meet the need for this product can be inferred from the following figures. More than one million doses of gamma globulin surplus to the needs of the armed forces have been distributed by the Red Cross since 1944 and approximately 600,000 doses in the first six months of 1948 alone. Gamma globulin has been particularly useful in the control of measles in children's hospitals, because of its potency and safety.

Subsequently, the value of this fraction in the prevention and modification of epidemic hepatitis was likewise demonstrated in three outbreaks.[29] Table 3 summarizes present knowledge on the usefulness of gamma globulin in various infections.

Just as the potency of fraction I in hemophilia depends on the freshness of the plasma from which it comes, the antibody titer of a gamma globulin preparation will depend on the titer of the plasma from which it is derived. In certain instances—notably mumps and scarlet fever—antibodies are present in the blood of normal adults in relatively low titer. However, they are present in much higher concentration in the blood of patients convalescent from these infections, and gamma globulins from convalescent plasma will have a correspondingly higher titer (fig. 2). Such convalescent mumps gamma globulin has been shown to reduce the incidence of orchitis in adult male patients with mumps, although ordinary gamma globulin is ineffective.[30] In the case of pertussis, hyperimmunization of adults with Hemophilus pertussis vaccine has been used to obtain hyperimmune human serum for prevention and treatment of the disease. A gamma globulin concentrated from such plasma is being used instead of the bulkier serum, thus giving a much smaller dose for injection.[31]

4. *Serum Albumin.*—Serum albumin was originally developed as a blood substitute for the emergency treatment of shock in the wounded.[32] In this form it was dissolved in a twice-isotonic sodium chloride solution containing a mercurial bacteriostatic preservative. Subsequently its use in hypoproteinemic edema and nephrosis led to the preparation of a salt-poor albumin solution, in which the sodium content is one-seventh that of an osmotically equivalent volume of plasma and in which stabilization has made possible heating at 60 C. of ten hours.[33] This procedure, which has been shown to inactivate the virus of serum hepatitis,[34] and is adequate to destroy vegetative forms of many bacteria, permits the omission of the preservative. All albumin being produced now conforms to the specifications for low salt, mercurial-free serum albumin.

The value of serum albumin in the treatment of shock due to loss of blood depends on its effectiveness, convenience and safety. It suffers from the same defect as plasma, a lack of oxygen-carrying power, but does not transmit jaundice and is easier to transport and administer. Studies have indicated that in most cases of shock, unless additional sodium chloride solution is given (400 cc. to 25 Gm. of albumin) the full plasma volume increase of 18 cc. per gram of injected albumin will not be achieved, although on the average an increase of 10 to 12 cc. per gram will be observed.[35] However, the low viscosity of albumin makes it harmless even in concentrated solution.

During the past year and a half, distribution of serum albumin, prepared from surplus plasma which was pyrogenic or otherwise unsatisfactory, by the American Red Cross, has enabled investigators in teaching hospitals all over the country to study its physiologic and therapeutic value in a wide variety of conditions. The results of these studies will be summarized in a subsequent report, but some of the individual investigations are already in press or published.

Metabolic studies of the fate of albumin are laborious, but extremely important in understanding the relation between circulating albumin and the body protein stores. In rats, human serum albumin is an incomplete protein which must be supplemented with isoleucine and tryptophane if it is to promote growth and build new tissue protein.[36] Comparable studies in human beings have not been made. When fed to human subjects, serum albumin leads to an increase in nitrogen excretion such as would occur with any addition to dietary protein. When the albumin is injected, no such rise in nitrogen excretion occurs, and there is almost quantitative retention of the injected nitrogen. There is a rise in total circulating albumin and plasma volume which will account for only a portion of the injected protein.[37] Exactly where the remainder goes is an unsolved problem. The extent to which it is stored as albumin or smaller fragments in interstitial fluid or tissues, burned to yield energy or converted to tissue protein is under active investigation by several groups.[38] One interesting observation which has been made is that profuse albuminuria may develop when the concentration of albumin is pushed to abnormally high levels in patients with apparently normal kidneys.[39] Further studies will be needed to clarify the metabolic role of serum albumin.

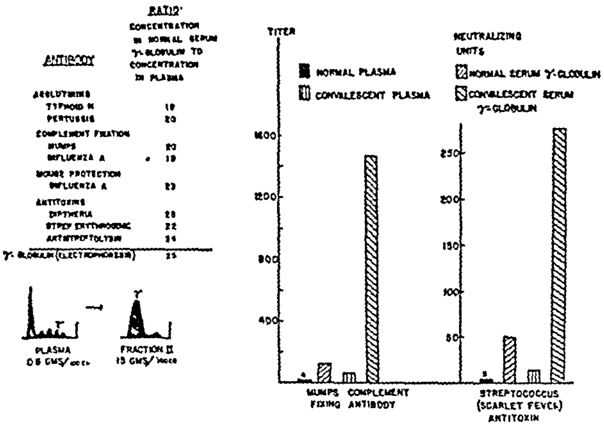

Fig. 2.—Concentration of antibody in normal serum gamma globulin and comparison between antibody titer of gamma globulin derived from normal plasma and that from mumps and scarlet fever convalescent plasmas.

The therapeutic indication for albumin is to sustain or restore the level of circulating albumin, if physiologic

disturbances result from hypoalbuminemia. When the latter develops acutely, as in severe infections, burns, peritonitis or abdominal or thoracic operations, therapy is apt to be most effective. Large doses, 50 to 100 Gm. in twenty-four hours, and a high caloric intake, are needed to obtain maximum benefit. Albumin, which comes in 5 Gm. as well as 25 Gm. vials, is useful in pediatric patients because of its ease of administration, freedom from reactions and ready miscibility with other parenteral solutions. In some instances it has been used to mobilize fluid and relieve oliguria or to reduce local edema at such sites as the stoma of an intestinal anastomosis in patients with acute hypoproteinemia.[40] For its osmotic properties to be effective in getting rid of edema, the heart and kidneys must be capable of responding to an increase in plasma volume.

In chronic forms of hypoalbuminemia, the situation is more complex. In nephrosis, for example, the injected protein appears almost quantitatively in the urine and little elevation of the serum protein level follows daily injections.[41] Nevertheless, in my experience, many patients receiving an adequate dose of albumin, which is large and approaches the level of tolerance (15 Gm. a day under 4 years, 25 Gm. a day from 4 to 12 years of age and 50 Gm. over 12) will experience a slow diuresis as long as albumin therapy is continued.[42]

In general, diuresis has been observed only after about half of the courses administered. Caution must be observed in the administration of albumin to patients with hypertension. As yet, no evidence of permanent renal injury from albumin has been observed, but hematuria and nitrogen retention have developed in a few patients and further observation will be required to settle this point. The place of albumin in the therapy of nephrosis is limited. It is enormously wasteful and expensive; it does not alter the course of the disease, so far as we know, and subjects the child to a series of intravenous infusions. On the other hand, in certain cases in which other methods of therapy fail and in which edema is really incapacitating, my colleagues and I have found it useful. Rigid restriction of the sodium intake and the prevention and prompt treatment of intercurrent infections are essential in treating children with nephrosis.

The other major cause of chronic hypoalbuminemia is cirrhosis of the liver. Albumin therapy will elevate the serum albumin level to normal if daily doses of 50 Gm. are given for a period of one to two weeks.[43] This is followed by diuresis and disappearance of ascites in some patients, but not in others.[44] Two factors which seem to affect the results are the intake of sodium and the extent to which albumin accumulates in the ascitic fluid, thus raising its oncotic pressure. The most serious reaction observed has been hematemesis in a few patients with large esophageal varices.[32]

The value of concentrated albumin to relieve local or general edema of the brain in patients who have had cerebral trauma or operations is under study. Most neurosurgeons who have used it are convinced that it produces improvement more sustained than that following treatment with hypertonic dextrose, but more concrete evidence is needed before its general use is recommended.[45]

In this paper I have considered albumin as an inert colloid, given to restore osmotic relationships to normal. Presumably other colloids, such as globin, gelatin or gum acacia, might have the same effect. However, one must not lose sight of the fact that serum albumin is a physiologic substance, normally present in blood at a concentration of 4 to 5 per cent. Its osmotic function is best known, but serum albumin has been shown to have an important capacity, frequently rather specific, to bind, and thus presumably to transport in a physiologic manner, many substances of low molecular weight.[46] Thus, fatty acids,[47] naphthoquinones, such as the antimalarial drugs,[48] sulfonamide drugs,[49] mercury[50] and penicillin K[51] are substances for which these binding reactions have been studied. Moreover interactions of one plasma protein with another are just beginning to be investigated. Little clinical research has been devoted to this aspect of the function of albumin. It should not be forgotten, when the use of other substances having grossly similar osmotic properties is enthusiastically endorsed, that the fine structure of human serum albumin was developed by a long process of evolution to meet certain physiologic needs.

COMMENT

Two years ago this subject was presented before this assembly at the San Francisco meeting. At that time, it was pointed out that a large scale program of blood collection and processing would be necessary if physicians caring for our civilian population were to have the same opportunity for therapy and research with blood and its derivatives which was open to those connected with the armed forces during the war. During the past few years the American Red Cross has returned approximately four million packages of dried plasma and over one million doses of gamma globulin to the physicians of this country for the treatment of their patients. It has stimulated research on important practical problems, such as homologous serum jaundice, and has provided fraction I, gamma globulin, normal serum albumin and other blood derivatives to investigators all over the country for studies which have steadily expanded and defined the physiologic function and therapeutic value of many of the blood proteins. As the value of blood derivatives, prepared from a large backlog of surplus blood collected during the war, has been established and as that surplus has dwindled, the question of what would be done to provide these derivatives in the future has demanded an answer. A year ago, after prior consultation with and approval from the American Medical Association and other interested organizations, a National Blood Program was adopted by the American Red Cross. This program, not to be confused with the so-called permissive program, in which a local Red Cross chapter merely contracts to obtain donors for a community blood bank, is slowly getting under way. It is a broad program in which the collection of blood from voluntary donors in regional centers is used to meet the needs of local hospitals and physicians for whole blood and to supply material for processing to blood derivatives on the large scale required for economy. Research on methods of processing, on red cell preservation and on the development of new derivatives and the provision of material to qualified investigators are integral parts of this plan. Locally the medical supervision of the regional center is in the hands of a committee of the county medical society, as it should be, although obviously certain technical practices will have to conform to national standards. No regional center can be started without the approval of the local medical society, hospital association and health department. Such a program does not contemplate the destruction of existing local blood banks which are meeting the needs of the community, but is working toward supplementing them so as to provide not only a national network of blood banks in case of disaster but also the possibility of blood collection on the scale requisite to procure the amounts of blood and its derivatives needed to keep pace with advances in medical and surgical practice.

No better statement of the basis for the development and use of blood derivatives has been made than by Prof. Edwin J. Cohn,[4c] whose researches have been responsible for the development of human plasma fractionation:

> Starting with the assumption, which must for the present remain an assumption, that every part of the human blood performs an important natural function—that the amount of any plasma component that may wisely be used in replacement therapy is the amount that will tend to reestablish rather than to derange the normal concentrations of the various physiologically significant plasma components—we have attempted to make available as many as possible of its diverse protein components, separated and concentrated as specific therapeutic agents, of value in different conditions, in the interest of the most effective and economical use by a society of the blood which it contributes.

SUMMARY

An attempt has been made to survey the field of blood derivatives. Like all active areas of investigation, it is in a state of flux. However, enough has been accomplished in a decade to establish certain derivatives, such as red cell suspensions, plasma, fraction I, fibrin foam with thrombin, fibrin film, gamma globulin, isohemagglutinins and serum albumin, as valuable therapeutic agents. The use of blood derivatives depends on an appreciation of the fact that deficiencies of one or another of the physiologic functions of the blood occur because of a lack of the specific components, usually proteins, which mediate them.

CLINICAL MANIFESTATIONS OF INFECTION WITH POLIOMYELITIS VIRUS

ALBERT E. CASEY, M.D.
Birmingham, Ala.
WILLIAM I. FISHBEIN, M.D.
FRANCIS B. GORDON, M.D.
Chicago
and
FRANK M. SCHABEL Jr., M.D.
Birmingham, Ala.

HERMAN N. BUNDESEN, M.D., Sc.D.
Chicago

Most of the clinical observations on poliomyelitis have been limited to that relatively rare form of the disease which results in residual paralysis. Even here no controlled observations have been published which enable one to say whether a great variety of symptoms are really typical of this disease. For instance, current articles in the foreign and American literature list diarrhea, sore throat, running nose and cough as symptoms of poliomyelitis, but offer no proof. It may be said with safety that outside of paralysis or paresis in a child with an acute febrile illness resulting in head drop, stiff neck and stiff back, and usually accompanied with moderate increase in the spinal fluid protein or cells, no symptoms have been firmly established. Children without these signs from whom the virus has been recovered have often been erroneously called "healthy carriers."

In the special survey of poliomyelitis which has been conducted in Chicago during the past three years, controlled field experiments were planned to elucidate the symptoms of all forms, but especially of the subclinical variety.[1] Subclinical poliomyelitis may be defined as poliomyelitis without stiff neck, stiff back, paralysis or obvious paresis. It is the common or usual manifestation in persons infected with this virus, and a comparison of the symptoms in the subclinical and clinical forms is herein presented.

MATERIAL AND METHODS

The material consists of 64 cases of subclinical and 33 of clinical poliomyelitis from twenty-one Chicago neighborhoods during 1945 and 1946. It was controlled by parallel observations on 157 noncontact or control children from the same

---

The work was aided by a grant from the National Foundation for Infantile Paralysis, Inc., and its Cook County chapter.

Read before the Section on Pediatrics at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

Six tables giving clinical, epidemiologic and virologic data on the 254 children are included in the reprints, which are obtainable from the authors.

From the laboratories of the Chicago Health Department, The Birmingham Baptist Hospitals and the Department of Bacteriology, University of Chicago.

neighborhoods, making a total of 254 children in the study. The neighborhood was that area within one block's radius of the residence of a reported paralytic case of poliomyelitis. The *field*[2] *and laboratory*[3] *technics have been described.*

Daily clinical observations, including axillary temperatures, were made on a number of children from the fifth to the twenty-first day after known intimate exposure to another child in the infectious stage (i. e., five days before to five days after the onset)[4] of poliomyelitis. Similar studies were made on noncontact subjects in the same and on controls in neighborhoods ten or fifty blocks distant. Noncontact subjects and control subjects were children of similar age and sex as the contact subjects but differing in that no intimate association could be established with another child in the infectious stage of either clinical or subclinical poliomyelitis.

Infection with poliomyelitis virus was said to have occurred if the virus could be recovered from the stool or throat (50 children), or if an elevation of the spinal fluid protein above 35 mg. occurred within twenty-one to forty-five days after exposure to the person with infectious disease. Two "noncontact" children from whom the virus was recovered (7 per cent) and their intimate contact sources were eliminated from this report as were a group of contacts from whom the virus could not be recovered or elevated spinal fluid protein demonstrated. Omitted are 30 contact children believed to have contracted subclinical poliomyelitis and from whom nose, throat and stool specimens were collected, which, at the time of reporting, had not yet been inoculated into monkeys. Several hundred other contact children from the same neighborhoods, but without the benefit of temperature, spinal fluid or virus data, likewise are omitted.

The stools to be tested were received by the virologists (F. B. G. and F. M. S.) in 50 per cent glycerin in isotonic sodium chloride solution and were emulsified in water and centrifuged at about 3,000 revolutions per minute for thirty minutes. The supernatant was dialyzed against distilled water at 4 to 8 C. for eighteen to twenty-four hours, removed and separated into two portions. One portion was designated "raw" and stored. The other portion was mixed with approximately equal volumes of absolute diethyl ether and shaken mechanically for twenty to thirty minutes. The ether was allowed to layer out, and the aqueous phase was cultured in a fluid thioglycollate medium. Specimens showing no bacterial growth in this medium after eighteen to twenty-four hours' incubation were considered to contain bacteria in numbers small enough to allow inoculation of monkeys. Specimens were shaken daily with ether until the point of concentration of viable bacteria described previously was attained. The aqueous phase was drawn off and residual ether removed under decreased atmospheric pressure. All specimens were stored in a frozen state of approximately — 20 C. until inoculated into monkeys.

Three species of monkeys were used in the study: (1) Macaca mulatta (Rhesus), (2) Macaca cynomolgus and (3) Cercocebus fuliginosus (sooty mangabey). Each specimen was tested for virus by inoculation of 2 monkeys by the following routes: intracerebral and intraperitoneal inoculation with the ether-treated material and intranasal inoculation with the "raw" material. Daily temperature records and observations were made on each animal for a period of twenty-one days (or until clinical signs of poliomyelitis were obvious), at which time the animals were killed and representative samples of the neuraxis were taken for histologic examination.[5]

Throat specimens were treated exactly as the stool specimens except that the preliminary emulsification and centrifugation were omitted.

The virus of poliomyelitis was recovered from stools collected during the observation period on 50 of the contact children; 10 other contact children in the field study (4 of whom had not yet been tested for virus) had delayed spinal fluid protein values elevated above 35 mg. Eight additional children who had had intimate contact with infectious patients in the same neighborhoods were recovering or had recovered from minor illnesses without paralysis or stiff neck when the study began. The spinal fluid protein values were elevated above 35 mg. in each. The illness in 4 of the 60 contact subjects in the field study was associated with stiff neck, in 1 with paralysis. Sixty-four children, none of whom had stiff neck, stiff back or paralysis, are considered to have had subclinical poliomyelitis.

There were 33 children from the twenty-one neighborhoods (the 24 original subjects with paralytic disease which attracted us to the particular neighborhoods for a field study and 9 with clinical conditions discovered in the neighborhoods by the field study including the 4 previously mentioned). Each patient with clinical poliomyelitis was admitted to a hospital where thorough clinical and laboratory studies were made (29 were admitted to the Municipal Contagious Disease Hospital, under the direct supervision of Drs. Archibald Hoyne and R. Brown and their staff, and 1 each to Cook County, Children's Memorial and Evanston hospitals).

As already mentioned there were 157 noncontact and control children in the study. Virus was not recovered from the stools, and the spinal fluid protein was not found elevated in 33 noncontact and control children from the same neighborhoods about whom careful field studies failed to establish association with a clinical or subclinical case of poliomyelitis in the infectious period.

Since virus was found in only 7 per cent of the noncontact children examined we added as controls 124 additional children from the same neighborhood studies. Thirty-three were noncontact children of whom temperature and field studies were carried out and from whom nose, throat and stool specimens were collected, but not yet used for inoculation in monkeys; 43 were control children from the 1945 studies and 48 control children from the 1946 studies. These children resided ten or fifty blocks distant from the thirteen poliomyelitis neighborhoods and were chosen for the purpose of sampling virus distribution in the city and for comparing illnesses in such children with those occurring among the noncontact children in the same block as the poliomyelitis patient. The inclusion of these 124 children possibly adds 5 to 8 children from whom poliomyelitis virus may be obtained when our animal inoculations are completed. However, such a small group should not significantly affect our comparative results except to diminish rather than to add to the significance of the symptoms.

Because we wanted to avoid biased clinical observations in our field studies we enlisted the aid of four pediatricians with special training in poliomyelitis (Martin B. Andelman, Irving Abrams, Herman Lander and Arnold P. Drucker), who checked in the neighborhood or in the hospital every illness and suspected illness among the 254 contact, noncontact and control children whose case histories are herein reported. They examined carefully for paresis, paralysis, reflex changes, head drop, stiff neck, stiff back and other clinical features. In addition, each contact, noncontact and control child had, during the period of five to twenty-one days after known exposure to an infectious patient, daily axillary temperature taken and nose, throat and stool specimens collected, and clinical observations were recorded by the field nurses and the field investigators. (The nurses chiefly responsible were Minnie Altiere, Arlene Ross, Audrey Korwin, Lydia Goltz, Florence Brock and Amy Quinlan.) All the children in each of the contact and control neighborhoods herein reported were personally investigated by the senior author, usually by many repeated visits to friends, neighbors and families.

RESULTS

There was no significant difference in the incidence of fever, leg ache, headache, sore throat, vomiting, constipation, diarrhea, running nose, cough or drowsiness between the noncontact patients in 1945-1946 the results for whom were negative for virus and elevated spinal fluid protein and the 43 control subjects for 1945, the 33 noncontact patients for 1946 and the 48 control subjects for 1946, none of whose stools had been injected into monkeys. Three children in the 1946 control group said to have been listless in the field protocols were classified as drowsy, and this error was shown in the calculations. Also, in 4 of the 1945 subjects pertussis developed during the study, and vomiting was therefore prominent. Since the symptoms in the various control and noncontact groups were essentially homogeneous, these were combined in order to swell the controls for the comparisons with the symptoms in children from whom virus was recovered.

The incidence of the various symptoms and signs in the 157 control and noncontact children was compared with the incidence of various symptoms and signs in the 64 contact children with subclinical poliomyelitis. Fever (almost invariably mild), headache, constipation and drowsiness occurred significantly more often among the children with subclinical poliomyelitis than among the control group. Vomiting, though only probably significant in the entire group, was statistically significant when the 4 pertussis cases were eliminated, or when the incidence was compared directly with that in the 33 noncontact and control children already tested for virus.

Noteworthy was the fact that sore throat, diarrhea, running nose and cough were [illegible] related to the symptoms of subclinical [illegible] was evidence that diarrhea, running nose and cough were significantly not related to this disease. Leg ache was observed too infrequently to be of significance.

The symptoms in the patients with clinical poliomyelitis were then compared with those in the control group. Again running nose, diarrhea and cough were not symptoms of clinical poliomyelitis, but sore throat and leg ache were. The symptoms of headache, vomiting, constipation, drowsiness and mild fever were of statistical significance as in the subclinical form. The difference was that headache, vomiting, constipation, drowsiness, fever and leg ache were more often encountered in the clinical than in the subclinical form. It is interesting that sore throat had no relation to the symptoms of the patients with the subclinical form of poliomyelitis but was often present in children who had stiff neck, stiff back, head drop and paralysis. Furthermore, careful notations at the Municipal Contagious Disease Hospital illustrate the frequency of a visibly red throat in the clinical form. If aches in the muscles of the abdomen and upper extremities were added to those of the lower extremities, myalgia would be a significant symptom in the subclinical as well as the clinical form. Pain along the cervical part of the spine was not infrequent.

COMMENT

Of the 64 children with subclinical poliomyelitis, 16 (25 per cent) presented no symptoms or signs of fever, headache, vomiting, constipation or drowsiness; 8 additional children had fever detected only by the nurses' taking the daily axillary temperatures and not recognized by the patient or by the mother. This made a total of 24 children (38 per cent) who had no reported subjective symptoms whatever. Twenty-two of the 24 children without professed symptoms were 6 years of age, or under (92 per cent), whereas only 24 of 40 children with symptoms were 6 years of age or under. This difference is statistically significant ($X^2 = 7.4$; $n = 1$; $P = 0.01$ —).

To determine whether the subclinical illness was less severe among the preschool children than among those over 6 years of age, the 39 children without history of prior illness or fever were analyzed. Fever was observed by axillary temperature determinations in 5 of 9 children over 6 years of age and in 16 of 30 children 6 years of age and under. Fever was of almost identical incidence in the two groups ($X^2 = 0.013$; $n = 1$). It would seem, therefore, as one might expect, that the preschool children were not as accurate in reporting their symptoms as the older children. An error in our field method was detected in that mothers sometimes noted, with their own thermometers, fevers in the evenings in children when normal readings were made in the nurses' daily visits. These evening fevers were more frequent among the contact than among the control children, and we would recommend afternoon and evening temperature readings for three weeks after exposure to an infectious patient.

The incidence of 1 case of paralytic disease (2 per cent) and 3 of meningitic disease (5 per cent) to 56 cases of subclinical disease (93 per cent), as determined by the virus study, is in close accord with the estimates derived from the field histories and temperature studies already published.[6]

Current studies by our group (unpublished material) on the incidence of stool versus mouth and throat virus in children with the clinical and subclinical disease indicate that the stool virus is present in both groups in apparently the same frequency. However, the virus was recovered from the throat in each of the aforementioned 4 paralytic and meningitic patients (100 per cent) with the clinical disease tested in the last five days of the incubation period and in only about 33 per cent of children with the subclinical form of poliomyelitis.[7] This may explain why sore throat is a symptom of the clinical but not of the subclinical variety. It may also explain why it was possible in earlier studies in Walker County, Ala., to trace a paralytic or meningitic case to contact with a prior paralytic or meningitic case with more ease than to a prior subclinical case.[8] It might also explain why poliomyelitis seems to burn out in a given neighborhood or area if transmission is largely through clinical cases. This would seem to substantiate the importance of the throat and mouth in the contact transmission and minimize the importance of the stool virus in modern communities. This need not predicate that the virus is not present in the throat in the usual subclinical case, but only that it is not easily recovered by swabs or transmitted to another child. Perhaps the severity of throat symptoms is usually directly proportioned to the amount of virus present in the throat and underlying nervous system.

Acute febrile illnesses, without paralysis, of sudden onset and of eighteen to seventy-two hours' duration, among the contacts of poliomyelitis patients have long been recognized.[9] The symptoms of headache, vomiting, sore throat, malaise, drowsiness, reddened throat and enlarged lymph nodes have been described. Estimates of the frequency of such cases have gradually increased during the years: 1:1 or 2:1,[9a] 2:1 or 4:1,[9c,d] and 6:1 or 14:1.[9e] Because the head drop, stiff neck and stiff back were so characteristic, no clinical diagnoses of nonparalytic poliomyelitis were generally considered tenable without these observations. The other symptoms have been considered too speculative for clinical use.

The literature contains only isolated instances of minor illnesses among contact subjects without stiff back, stiff neck and without paralysis, which were proved by the recovery of the virus or by demonstration of a rise in spinal fluid protein. Taylor and Amoss [9g] in 1917 recovered the virus from the throat of a child contact (white boy, aged 10 years) several days before fever of short duration and diarrhea developed. There was no stiff back, stiff neck or paralysis and no other symptoms. Paul and Trask [9e] recovered virus from the throat of 2 contact subjects without paralysis or stiff neck. The first, a white male infant of 13 months, had fever and drowsiness and the reaction of the spinal fluid was negative immediately; the second, a white boy aged 5 years, had fever of eighteen hours' duration and vomiting. Paul, Trask and Webster [9h] obtained the virus from the throat of a contact subject in whom nausea, headache, fever, anorexia and pains in the legs and back developed, with the immediate reaction of the spinal fluid negative and no stiff neck, stiff back, paralysis or weakness. Langmuir [9i] recovered virus from the stool of 10 contact subjects without stiff neck, stiff back or paralysis. Four of the 10 experienced vomiting and abdominal pain, 1 fever and vomiting, 1 pain in the knees and backache and 1 headache, pain in the eyes, dizziness and soreness in the chest and abdomen; 2 had "mild upper respiratory symptoms" and were not confined to bed. Of the 14 children described, 5 had fever of short duration, 6 experienced vomiting, 2 headache, 4 abdominal pain, 2 pains in the legs and 2 pains in the back. The low incidence of fever may be due to the lack of systematic field study, and the high incidence of other symptoms to the failure to study the stools of many asymptomatic infants for virus. The symptoms detected are entirely compatible with our own observations.

Ours is, however, the first controlled series of children with subclinical poliomyelitis studied during the incubation and disease periods and proved by virus and spinal fluid studies.

SUMMARY AND CONCLUSIONS

The symptoms reported by 97 children with poliomyelitis are compared with those among 66 noncontact children living in the same block with the patients, and among 91 control children living in neighborhoods ten or fifty blocks distant. Poliomyelitis was proved in each child by the recovery of virus from the stool or throat and/or by the occurrence of elevated levels of spinal fluid protein twenty-one to forty-five days after intimate contact with an infectious patient.

Thirty-three of the 97 had clinical poliomyelitis characterized by paralysis, paresis, head drop, stiff neck or stiff back. The remaining 64 were intimate contacts of infectious patients in whom subclinical poliomyelitis characterized by an absence of the aforementioned signs developed within five to twenty-one days after exposure.

No differences in the symptoms between the noncontact children and the controls were detected. Mild fever of short duration, headache, vomiting, constipation, myalgia and drowsiness characterized both the clinical and the subclinical forms of poliomyelitis, the difference being one of degree and increased frequency among the former. Sore throat was definitely not a symptom of the subclinical variety, but was significantly related to stiff neck, stiff back and paralysis or paresis. The possibility is discussed that the presence of sore throat in clinical cases and its absence in subclinical cases might coincide with the quantity of virus present in the throat and in the nervous system, with the infectiousness and clinical severity and with certain epidemiologic features of the disease.

Running nose, diarrhea and cough were definitely not related to the symptoms of either clinical or subclinical poliomyelitis. Evidence of poliomyelitis among children 6 years of age and under is difficult to obtain without an adequate field study, even though 80 to 100 per cent of such children succumb on exposure. The younger patients are less likely to report minor symptoms described in almost every instance by older children.

Virus was recovered from the stool (50 children) and/or the spinal fluid protein was elevated above 35 mg. in 60 intimate contact sources of infectious patients in whom poliomyelitis developed within five to twenty-three days after known exposure. Four of the 60 children had the clinical disease (1 was paralytic [2 per cent] and the other 3 nonparalytic [5 per cent], with stiff neck, stiff back and head drop) and the remaining 56 had the usual or subclinical form of the disease (93 per cent).

ABSTRACT OF DISCUSSION

DR. HULDA E. THELANDER, San Francisco: Subclinical poliomyelitis in the environment of the paralytic patient is the logical clinical concept. The infectious agent is widely dispersed, but only a relatively small number of persons harboring the virus succumb to recognizable disease. This knowledge should alert one to considering more carefully the host and factors influencing susceptibility on the one hand and the possible variability of the infectious agent on the other. The literature makes frequent references to fatigue and trauma as factors predisposing the host to paralytic disease. Dr. Shaw and I have long maintained that bacterial infections at times may also be predisposing factors. Most of the cases in any epidemic season are almost completely devoid of any apparent infections of the respiratory or the intestinal tracts. There are, however, some patients with exudative sore throat or with diarrhea, and even pneumonia, preceding paralytic symptoms. It is likely that these symptoms represent concomitant infections which may actually alter the host's resistance to the virus of poliomyelitis. Such infections may even be the explanation of the so-called dromedary type of the disease. From experiments in animal passage, it is evident that viruses may alter their characteristics. How much human passage may result in alterations of the virus has not been determined. Does the present concept of poliomyelitis represent more accurate observations of the disease, or has the disease altered some of its manifestations through the years? This possibility should be carefully evaluated in recording observations for comparison with future studies; accurate clinical observations may contribute as much to progress in our knowledge of the disease as laboratory studies.

Dr. James P. Leake, Washington, D. C.: Poliomyelitis occurs at all times and in all places, permitting comparison of one epidemic area with another, but for comparison of the incidence in various climates and places, I think that one can count only paralytic cases, that is, cases in which there is definite demonstrable muscular weakness. As far as I know, this is the first time the incidence of symptoms has been statistically worked out. We are indebted to Drs. Casey, Bundesen and McCoy and all others that have labored so thoroughly on this. Their results coincide with what we have felt before. Dr. Thelander's caution of considering at least the possibility that many things that are usually attributed to a disease may be a preceding infection is worth taking into consideration.

Dr. C. H. Webb, Shreveport, La.: While the varied manifestations of infection with poliomyelitis virus and the frequency of subclinical disease are generally recognized, the need of definitive studies is evidenced by vague statements in the literature; for example, that in every epidemic 10 to 1,000 cases of mild disease occur for every case with paralysis. The incidence of subclinical infections reported by the authors among the contacts as compared with noncontact children in the same neighborhood connotes important epidemiologic implications. The charts of 50 children whose disease was diagnosed as acute poliomyelitis by four pediatricians in the group observed by my co-workers and me were reviewed: 45 of these children have been seen since 1940; 33 were paralytic and 17 nonparalytic. Fever was listed in every instance, headache in 30 per cent, irritability in 32 per cent, sore throat or reddened pharynx in 28 per cent and drowsiness in 14 per cent. No significant variation was noted in these symptoms as between paralytic and nonparalytic children. Leg ache was complained of by 25 per cent of the paralytic patients, but by none of the nonparalytic. Vomiting occurred in 33 per cent of the paralytic patients and in only 12 per cent of the nonparalytic. Abdominal pain and constipation were noted in 15 and 9 per cent of the paralytic and rarely in the nonparalytic children. Diarrhea, coryza and cough were listed in less than 5 per cent of either group. It is worthy of note that convulsions occur rarely in poliomyelitis—only once in our 50 cases, in striking contrast to other acute infections of the central nervous system during childhood. During the summer of 1947, diagnostic difficulties were presented by the occurrence of a clinical syndrome of epidemic proportions, consisting of sudden high temperature, headache and occasional myalgia, lasting three to four days and clearing dramatically. Symptoms referable to the gastrointestinal or respiratory tract were rare. Successive sibling or contact cases suggested an incubation period of four to seven days. Adults were infrequently affected. Treatment with sulfonamide drugs or penicillin, when tried, was unavailing; laboratory observations were equivocal. In several instances, questionably stiff neck or back pains prompted spinal fluid examinations, results of which were normal. During the same period, in which we have records of 48 such cases and knew of over 100 more, poliomyelitis was at low ebb and no contact history could be established. We believe that this is a separate entity, probably of virus causation, and have recently described its clinical and epidemiologic features under the name "three day fever." It is intriguing to note its similarities to nonparalytic poliomyelitis and to herpetic pharyngitis, and yet distinctive features appear. It is hoped that virus studies can be made if a similar epidemic occurs. From the point of view of clinical research and experience, it would be important to evaluate all available methods by which viral infections may be differentiated from bacterial, in view of the general tendency to administer sulfonamide drugs and antibiotics to all acutely ill children. We are pursuing a study of atypical lymphocytes, heretofore described in infectious mononucleosis, measles, german measles and infectious hepatitis. To a varying degree we find that these cells occur in a number of infections in which the cause has been demonstrated or presumed to be viral, but rarely in bacterial infections.

Dr. Haddow M. Keith, Rochester, Minn.: Subclinical poliomyelitis is recognized only by recovering the virus from stools or from the throat or when the level of spinal fluid protein is elevated, other causes for this, of course, being ruled out. The method of proving subclinical infections is available mainly to groups having facilities to recover the virus; in other words to specially organized, trained and endowed groups. Perhaps the majority of children, then, have a mild form of subclinical poliomyelitis and therefore have immunity for a good many years. It has also been suggested that in crowded and unsanitary areas in the East, such as Cairo and Bombay, poliomyelitis is not a major problem, but in our American cities it has tended to increase within the past fifty years. Also there tends to be more poliomyelitis and severer poliomylitis in adults than there used to be. Are we by our effective public health measures against other diseases making poliomyelitis more of a problem than it used to be? If so, this means that we must direct our efforts toward a program of prevention, such as we conduct against smallpox or diphtheria. I would like to point out that neutralizing antibody tests reveal different strains of poliomyelitis virus, which may make a preventive program a little more difficult. I think that it is also true that the correlation of neutralizing antibodies and clinical immunity is not absolute and further studies are necessary along these lines. There is no doubt that there are numerous problems to be solved before poliomyelitis can be controlled effectively. It seems imperative, however, that the main effort be directed toward developing preventive procedures applicable in infants and children, such as have been developed against the other great epidemic diseases.

Dr. A. F. Abt, Chicago: The definitions submitted for subclinical and clinical poliomyelitis rather confused me. Of course, in pediatrics, there are continually changing definitions, with resultant confusion, but the long accepted definitions, as I knew them, consisted first of reported poliomyelitis, which is understood to be a systemic infection with no involvement of the central nervous system. Then comes a period of quiescence of symptoms, following which there is again fever, and then, as I take it, there are two types of infection—the nonparalytic and the paralytic. In the abortive type with systemic infection and no involvement of the central nervous system there is a clear normal spinal fluid, and we have no way of making a positive diagnosis of this type. What is needed is a quick and rapid method of isolating the virus, so that if one could distinguish this systemic involvement without involvement of the central nervous system, then one could probably evolve some form of treatment, but I do not feel that the treatment will ever be effective in the nonparalytic or paralytic stages.

Dr. Albert E. Casey: The point made by Dr. Thelander on the symptoms of concomitant infection and constitutional variation may explain some of the problems in this disease. The importance of differentiating between infection with stiff neck from infection without stiff neck is borne out by current studies in our group. This is unpublished material on the incidence of stool versus mouth and throat virus in children with the clinical and subclinical difficulties. These indicate that the stool virus is present in both groups. However, the virus was recovered in the throat in each of the aforementioned paralytic and meningitic patients but in only about 33 per cent of children with the subclinical form of poliomyelitis. This may explain why sore throat is a symptom of the clinical but not of the subclinical variety. It might also explain why poliomyelitis seems to burn out in a given neighborhood with transmissions largely from subjects with clinical infection. This would seem to substantiate the importance of throat and mouth and contact infection and minimize the importance of transmission in schools in the modern communities.

TREATMENT OF IDIOPATHIC PERNICIOUS ANEMIA

RUSSELL L. HADEN, M.D.
and
DONALD W. BORTZ, M.D.
Cleveland

Addisonian or idiopathic pernicious anemia is a complex disease resulting from a lack of specific factors necessary (1) for the normal growth and development of erythrocytes, (2) for the nutrition of nerves and spinal cord and (3) for the correct functioning of the gastrointestinal tract. With a deficiency of such factors (1) large uncompleted red cells stagnate in the marrow which becomes hyperplastic and red—such erythrocytes as are released into the circulation are macrocytic and so larger than normal, (2) the peripheral nerves and spinal cord degenerate from interference with nutrition and (3) the papillae of the tongue atrophy and the epithelial cells of the gastrointestinal tract become abnormal with impaired function. It is not known just how many factors are involved. There are certainly two and perhaps more. The disease was always fatal before the discovery of liver therapy. Over 10,000 persons died yearly in the United States alone before the epoch-making work of Whipple, Minot, and Murphy.

The clinical features of the disease are (1) macrocytic anemia, determined by count and measurement of the red cells, (2) subacute combined sclerosis of the spinal cord and peripheral neuritis, usually manifested first by a loss of vibratory sense, and (3) atrophy and soreness of the tongue, often diarrhea and digestive disturbances from impaired function of the stomach and intestinal tract, and a constant and absolute absence of free hydrochloric acid on gastric analysis. Not all patients show every manifestation. The combinations of symptoms and signs are varied; all, however, show the macrocytosis of red cells and achlorhydria. The patient is completely relieved of active disease by adequate liver therapy.

THE BONE MARROW LESION

In true idiopathic pernicious anemia there is a gradual lack of the specific factor needed for maturity of the red cells in the bone marrow. More young and incomplete erythrocytes which are larger than normal appear in the circulation. The number of circulating cells decreases also, so that there is macrocytic anemia. As the deficiency continues more and more immature large cells accumulate in the marrow, and the anemia of the peripheral blood becomes more pronounced. The examination of the bone marrow obtained by puncture shows many large megaloblasts and other macrocytes. The peripheral erythrocyte count becomes lower and lower. As the anemia progresses, the red cells continue large, and in time other abnormalities, such as poikilocytosis, anisocytosis, nucleated cells and basophilia, appear. These are late manifestations, however, and one should never wait for their appearance before making the diagnosis of pernicious anemia. The diagnosis should be made on the basis of manifestations of which the most important, so far as the blood is concerned, is the macrocytosis of red cells.

With macrocytic anemia there is usually leukopenia with increased maturity of the polymorphoneutrophilic cells. The leukocytes are retained in the hyperplastic red cell tissue longer than normal and thus become more mature, as shown by increased segmentation of the nucleus. Similarly, the development of megakaryocytes is interfered with and the number of platelets in the peripheral blood is reduced. The characteristic blood lesion then is macrocytic anemia with leukopenia and reduced platelet count.

THE NEUROLOGIC LESION

A high proportion of patients with well developed pernicious anemia complain of numbness and tingling of the hands and feet. Examination reveals that the vibratory sense in the lower legs is impaired. Later this becomes more widespread, the position sense of the feet is lost and still later there may be ataxia or spasticity with altered tendon reflexes due to impairment of the posterior and lateral columns of the spinal cord. Many patients with unrecognized or inadequately treated disease become unable to walk and are confined to bed.

THE GASTROINTESTINAL LESION

An almost constant observation in untreated or incompletely treated pernicious anemia is a clean smooth tongue, due to atrophy of the papillae. With this atrophy, real glossitis develops. This also is due to the lack of specific factors necessary for the normal nutrition of the tongue.

There is always achlorhydria. This seems a primary lesion with atrophy of the mucosa of the stomach and subsequent loss of gastric ferments. Many available data indicate that a patient with pernicious anemia has always lacked free hydrochloric acid. Every patient suspected of having pernicious anemia should have a test meal as well as careful study of blood and bone marrow. The mucosa of the small bowel also becomes atrophic and does not function normally. Absorption is faulty, leading to digestive disturbances and impaired nutrition. Diarrhea often develops.

The deficiency in pernicious anemia is quantitative. If untreated, it gradually becomes worse, with more serious symptoms. The blood lesion can be completely reversed with a return of the blood to normal. The anemia, leukopenia and thrombopenia all disappear, leaving no trace of the former deficiency. The bone marrow also becomes normal. The achlorhydria is permanent. Free hydrochloric acid never reappears in the stomach, regardless of intensive therapy.

COURSE OF EVENTS IN PERNICIOUS ANEMIA

The primary defect in pernicious anemia is a deficiency in a secretion of the stomach mucosa, the intrinsic factor of Castle, which acts on ingested food to form the substance or substances necessary for normal nutrition of bone marrow, nervous system, tongue and gastrointestinal tract. The intrinsic factor is probably a ferment.

Liver therapy completely relieves the deficiency in all three systems. This was at first thought due to a direct supply by the liver of a maturing factor or factors. It seems apparent that liver extract acts through some other mechanism and not by actually furnishing the missing factor or factors.

The discovery of folic acid throws further light on the problem. It has been observed that this may replace liver extract in relieving the anemia and thus may be the specific erythrocyte-maturing factor missing in the bone marrow. It may become a part of the erythrocyte

stroma. Potent liver extract contains only a minimum of folic acid and not enough for the action observed. Moreover, it does not protect against a neurologic lesion, so that it is evidently not the specific element needed for the nutrition of nerve tissue. It may cause the gastrointestinal tract to return to normal. It seems probable that liver extract acts through an enzyme system enabling the body to release the specific principles needed from stores of bound substances in the body. This explains its action in relieving all the deficiencies involving the blood, nervous system and gastrointestinal tract without actually supplying the needed substances.

The defect arising primarily in the stomach in true addisonian pernicious anemia may arise secondarily in other diseases, such as sprue, or after operation on the gastrointestinal tract. Here the defect is not due to lack of formation but to lack of absorption or utilization or to increased need, as in pregnancy.

How should this complex deficiency which is called pernicious anemia be treated? In idiopathic pernicious anemia the initial defect is permanent. There is no evidence that the missing factor in the stomach, which is primarily at fault, ever returns. Treatment must be adequate and permanent. The amount of deficiency is variable, so that it is difficult to gage the need. The important point in therapy is to treat fully and permanently. Since one cannot accurately gage the need for specific treatment, it is best to give enough treatment to cover all possible needs. Overtreatment does no harm, while undertreatment often leads to serious disability. Often less treatment is required to relieve the blood lesion than is needed to prevent or relieve the neurologic lesion. Every student of the disease is constantly confronted with patients who have had enough treatment to prevent significant anemia but present a disabling cord lesion while the insufficient treatment is being carried on. Since the cord lesion may be irreversible, often the patient remains a cripple regardless of the intensity of treatment.

The degree of involvement of the three systems is variable. There may be little anemia with much neurologic disturbance. The anemia may be extreme with no demonstrable neurologic disturbance; thus all combinations are possible.

Many methods of treatment are now available—whole liver, oral liver extracts, parenteral liver extracts, stomach extracts, folic acid and accessory substances, such as iron, hydrochloric acid and vitamin preparations, are offered for selection. The suggestions given are based on experience with more than 600 patients with true addisonian pernicious anemia by one of us (R. L. H.) and on recent discussions with numerous hematologists having a wide interest in this disease.

Whole liver is an excellent source of protein food besides having the specific action of liver. It is helpful for a person suffering from pernicious anemia to include liver in the diet, but it is not satisfactory for complete treatment. Stomach extracts can be given only orally, so that they are not desirable for the treatment of pernicious anemia. Oral liver extracts are often disagreeable to take, are much less potent than parenteral liver extracts and depend on absorption from the gastrointestinal tract. Treatment with oral liver extract is also more expensive than parenteral therapy.

Parenteral administration of liver extract is the treatment of choice for pernicious anemia. Unfortunately, extracts of many different unitages are offered the physician. The most desirable extract contains 15 antianemic units per cubic centimeter. It has been found difficult to make preparations of more potency. There is no reason to use a weaker extract, such as 1, 2, 5 or 10 units, or stronger extracts, containing more than 15 units per cubic centimeter. The problem is complicated only by using extracts of low and varying potency. These are provided entirely to meet competition among drug houses and not to supply real needs of the patient. Unfortunately, all liver extracts have to be standardized on patients. It seems evident that a unit is not always the same, although theoretically it represents the daily need. It is important to select a potent extract containing 15 units per cubic centimeter and to continue the use of this preparation, since one soon learns what to expect from a preparation of dependable constancy.

How should this liver extract be prescribed? There is no way to determine exactly the amount of specific principle needed to supply the deficiency. Any excess given is not excreted, and when treatment is begun the body is usually completely void of the needed factor. It is doubtful whether symptoms develop until the deficiency is absolute. The results of incomplete therapy are serious, often leading to permanent disability from a cord lesion, and overtreatment is always indicated. There is no harm in overtreating, and additional liver extract is inexpensive. The first principle in treatment is to prescribe large amounts for a sufficiently long time. There is no way to be exact in dosage. We insist, if possible, in hospitalizing the patient for the first two weeks of treatment. This gives an opportunity to follow the reticulocyte count, to gage the efficiency of response to treatment and to emphasize to the patient the seriousness of the disease. We have followed the principle of giving 15 units of extract daily for two weeks. A similar amount is prescribed twice a week for the remainder of a three month period. Weekly injections of 15 units are then given for three months, followed by twice monthly injections for six months. After this intensive treatment for one year, injections are given monthly for the remainder of the life of the patient. Usually 15 units are enough; 30 units will supply any need. Once the correct diagnosis of pernicious anemia is made, we know that the patient will always have pernicious anemia. There is no record of a recovery from true addisonian idiopathic pernicious anemia. The disease is not cured; there is only compensation for the deficiency by the administration of sufficient potent liver extract. Treatment must be constant and continuous through the life of the patient.

What results are obtained by adequate and complete therapy? The blood and bone marrow return completely to normal and remain so unless some other disease or factor disturbs the hematopoietic system. A neurologic lesion never develops under adequate and complete liver therapy. Usually a systematic improvement in an existing cord lesion occurs with intensive liver therapy, although the signs of cord involvement, such as absent vibratory sense and altered reflexes, usually persist. Only rarely does a patient remain disabled with proper therapy.

The achlorhydria always continues; the remainder of the gastrointestinal symptoms and signs disappear. The papillae of the tongue return to normal, the glossitis and diarrhea disappear, the body nutrition and absorption from the small intestine proceed normally and indigestion causes no more trouble.

The treatment of this serious disease is so satisfactory with complete liver extract therapy that the patient returns to normal and remains normal with continuous adequate therapy. There is no greater triumph in medicine than the marvelous response of this previously fatal disease to liver therapy.

Folic acid has already been mentioned as a possibly specific chemical substance needed by the bone marrow to complete the growth of red cells. According to this concept, it is actually incorporated into the red cell stroma to assure normal growth. Liver extract does not actually become a part of the cell stroma. Folic acid may cause the blood and marrow to return to normal, although the results are not so constant as with liver therapy. With adequate folic acid therapy the tongue and gastrointestinal tract may also return to normal. It is doubtful that a response on the part of the marrow and gastrointestinal tract is as satisfactory or constant as with liver therapy. In other types of macrocytic anemia, such as with sprue, the results may be even better with folic acid than with liver. The treatment of macrocytic anemias other than addisonian pernicious anemia is, however, another subject.

Folic acid does not influence the neurologic lesion. Many cases have been reported in which cord lesions have developed under folic acid therapy. The statement has been made that two thirds of the patients under folic acid treatment present a spinal cord lesion during adequate therapy. It seems probable that folic acid is in no way related to the cord lesion, but that some unidentified substance made available by liver therapy is the specific principle in the neurologic lesion.

We see no reason for depending on folic acid for the treatment of pernicious anemia. This point is emphasized by all competent observers. Is it of value to add folic acid to liver extract? There is no good evidence to support such a view if the liver therapy is complete. Folic acid only adds to the cost of treatment. With adequate and potent liver extract therapy the results in the treatment of pernicious anemia are so ideal that no change should be made at present.

Should auxiliary treatment be given? We see no reason to prescribe iron, hydrochloric acid, digestive ferments, mineral salts or vitamins. The patient should have a complete wholesome diet with adequate protein. Most patients will have good food intake spontaneously, since the appetite quickly improves and food is taken after adequate liver therapy.

An allergy rarely develops to parenteral liver extract. One can avoid the possibility usually by changing the type of liver extract. The reaction is due to the specific animal and not the liver as such. Since extracts from beef, hog, horse and sheep may be used, the allergy problem can almost always be managed. When the use of liver extracts parenterally is impossible, oral therapy should be tried with or without antihistaminic drugs, such as diphenhydramine hydrochloride ("benadryl hydrochloride") or tripelennamine hydrochloride ("pyrabenzamine hydrochloride"). The reaction from parenteral injections may be prevented by the addition of small amounts of epinephrine.

If all liver therapy is impossible, folic acid may then be used without influencing an existing neurologic lesion. Such a lesion is likely also to develop during adequate folic acid therapy. Some observers have expressed the thought that this development might be more possible with folic acid.

SUMMARY

Addisonian idiopathic pernicious anemia is a deficiency disease affecting the bone marrow, the nervous system and the gastrointestinal tract. This deficiency is responsible for the characteristic macrocytic anemia and megaloblastic bone marrow, the subacute combined sclerosis and peripheral neuritis, the glossitis and other gastrointestinal symptoms. The fundamental defect is in the stomach mucosa, and, once there, is always present.

All manifestations of the disease can be prevented and relieved by proper therapy. Treatment is necessary throughout the life of the patient if the diagnosis is correct. Liver therapy is perfect treatment with proper technic and a potent preparation. More than one substance is deficient, but all absent factors become available with liver therapy. Liver is best given as a potent extract parenterally. Treatment should be intensive at the onset to more than satisfy the deficiency. Treatment must be given regularly and adequately for the life of the patient. Folic acid is only partial therapy and does not relieve the deficiency responsible for the neurologic lesion, which is the most serious aspect of of the disease.

Until the introduction of liver therapy pernicious anemia was invariably fatal. The serious crippling lesion of the disease is involvement of the nervous system. This can be prevented and often helped by liver therapy but not by folic acid. A method for administering liver extract which has proved highly satisfactory for a large number of patients is outlined.

ABSTRACT OF DISCUSSION

Dr. Frank H. Bethell, Ann Arbor, Mich.: I agree with the speaker that no treatment other than with refined liver extract is ordinarily needed for pernicious anemia. Crude extracts have no advantages over the refined and concentrated types. Vitamins have no value except to relieve deficiency. I am not prepared to accept fifteen units per month as adequate treatment for the majority of patients with pernicious anemia. We have found that fifteen units twice a month is perhaps a safer dose, particularly since there are no ill effects from giving more treatment than is required. A careful hematologic examination is the only way one can measure the adequacy of maintenance therapy. It does not do to wait for the return of symptoms. A careful hematologic examination includes a determination of erythrocyte size by means either of diameter measurement or estimation of mean corpuscular volume. Unless cell size is within normal limits, the treatment cannot be said to be adequate. Folic acid, as Dr. Haden mentioned, has a distinctly limited field in the treatment of pernicious anemia; indeed, it is questionable whether it should ever be employed. It is about equally effective by both oral and parenteral routes of administration. Combinations of liver extract and folic acid are irrational, because of the different dose requirements and different excretion rates of the two substances. Folic acid should never be given to patients with evidence of nervous system disease, and others receiving it should be kept under close observation for development of neurologic manifestations. If such appear, folic acid therapy should be discontinued immediately and liver extract substituted for it. The recent announcement of a crystalline substance isolated from liver and tentatively named vitamin B_{12} may lead to complete revision of the specific treatment of pernicious anemia and related macrocytic anemias. This compound in our hands at Ann Arbor has induced optimal hemopoietic responses in patients with pernicious anemia in doses as small as 1 mg. daily. As the speaker indicated, medicinal iron preparations are not ordinarily valuable in the treatment of pernicious anemia. However, when hypochromia or a low color index is present after response to specific therapy, ferrous salts should be prescribed in divided daily doses of 1 to 2 Gm. Most female patients with pernicious anemia before the menopause benefit from the adjunct use of medicinal iron. Hydrochloric acid occasionally has a place in treatment, at least temporarily. A dose of 2 to 4 cc of the U. S. P. dilute solution given in water with meals may have a beneficial effect on digestion and aid in controlling diarrhea, especially in the early period of treatment. It has no specific value, and it usually can be discontinued without recurrence of digestive symptoms after remission is well established.

Dr. Howard L. Alt, Chicago: The considerable literature on the effect of folic acid in pernicious anemia has led to some confusion as to how this disease should be treated. For this reason, the paper of Drs. Haden and Bortz is timely in pointing out clearly the treatment of choice in pernicious anemia. Folic acid has been relegated to a rather insignificant place in treatment. My co-workers and I have not used intensive parenteral liver therapy for the period of time advocated by Dr. Haden. It has been our custom to give about 150 units of liver the first week and then 15 units once a week until the blood picture is normal and the cord symptoms and signs become static. In our experience, relapses are not uncommon with the parenteral administration of 15 units of liver once a month. On the other hand, 30 units every twenty-one days will maintain the disease in practically all cases in complete remission. I am glad that Dr. Haden pointed out the difference in potency of 15 unit liver preparations manufactured by different companies. It is wise to use a single preparation in order to know what that one will do. In maintaining patients in complete remission, a careful study of the symptoms, physical signs and the blood picture should be made every three or four months. We have found it useful to tabulate neural symptoms and signs, including a record as to whether the vibration sense is normal, diminished or absent from the iliac crests to the malleoli. A decreasing vibration sense is a sign of inadequate treatment. As the authors said, liver extract therapy completely controls the deficiency in pernicious anemia and cannot be replaced by folic acid therapy, which only partly controls the deficiency.

Dr. Hyman I. Goldstein, Camden, N. J.: In *The Review of Gastroenterology* (**9**:406-411 [Nov.-Dec.] 1942) I published an article, "Pernicious Anemia Alternating with Polycythemia (Polyglobulia)," and cited some cases of pernicious anemia in which a polycythemic response occurred during liver therapy. Has Dr. Haden met with such cases? Free hydrochloric acid was never noted in these cases. Dr. Haden decries the use of folic acid and (oral) hydrochloric acid and recommends the use of liberal parenteral doses of liver extract. Most of us are in accord with everything he propounded today. May I call attention to the early use of liver therapy in anemia by Paul Carnot, Maurice Perrin, of France, P. F. Castellino (1864-1933) and Alfonso Pirera (born Feb. 16, 1877) of Naples? Pirera fed dogs and rabbits liver (after they had been bled) and gave them injections of liver extract and liver juice (1910-1912). Perrin used liver and noted the improvement in the blood in patients with "alcoholic cirrhosis of the liver" (1904, 1905, 1908). Pirera (Tommasi **7**:601-617 and 625-636, 1912) noted that granulocytes were increased by liver therapy. In 1934, Murphy suggested the use of liver in granulocytopenia. James S. Combe (Tr. Med.-chir. Soc. Edinburgh **1**:194-204, 1824) reported a case of pernicious "idiopathic" anemia with necropsy long before Thomas Addison; and P. F. A. Marquis in 1846 wrote on "De l'influence de l'anémie sur le système nerveux," (Thesis, Paris, No. 1, 1846). No mention is made of the reports by E. Geddings (Baltimore M. & S. J. **2**:325-366, 1834) and "F.," a physician of Rhode Island (A Dissertation on Anemia, Boston M. & S. J. **20**: 101-108, 117-124 and 133-138, 1839). It is unfortunate that we are such poor linguists and so have overlooked and delayed the use of liver therapy in anemia for twenty or twenty-five years until the epoch-making article on liver feeding by Minot and Murphy appeared in The Journal August 14, 1926.

Dr. William P. Murphy, Boston: Through almost twenty-five years of experience in the treatment of pernicious anemia my colleagues and I have become convinced that it is one of the few diseases which can be treated entirely on a quantitative basis. There are few diseases in medicine which can be so treated, and it is up to us as individuals and also as a profession not to fumble the ball at this time, failing to treat our patients adequately or properly. Two circumstances make it possible and desirable to treat pernicious anemia on a quantitative basis. We have in this country liver extracts which are well standardized and well prepared. Unfortunately, there are few countries other than this where liver extracts are standardized. We also have available a simple and readily utilizable means of following the effect of treatment to determine whether or not it is adequate. In regard to liver extracts, I again wish to emphasize that the treatment of choice is by the parenteral route and with those extracts which are the most highly potent and refined rather than with the so-called crude extracts. A crude extract means simply that there are inert substances left in it which have no value in the treatment of pernicious anemia. One might say that it is crude therapy and not crude extract that we use at times. With the 15 unit, 1 cc. material, as a unit or basis for treatment, it has been our custom to give as initial treatment rather large doses. Thereafter we give 15 units each week, following the hemoglobin and erythrocyte levels at intervals of one to two months; as the levels reach or rise above normal, the interval between injections is increased. That is, we do not change the size of the dose, for I believe that there are certain objections to that in some patients, but we increase the interval between the dose up to two, three or four weeks, depending on the indications from the blood picture. This treatment is again followed for a period of months, during which time we check the blood at three month intervals. If the tendency is for the erythrocyte level to rise above the 5,000,000 mark, the interval between injections is increased; if the erythrocyte levels are falling during the sequence of counts, the interval between injections is shortened. In this way the blood levels are constantly under observation, making it possible for one to increase or decrease the intake of antipernicious anemia substance according to the need of each patient. Regulation of the dosage in this way, we believe, is the best assurance of an adequate supply of liver extract to prevent or to improve the difficulties which may result from spinal cord damage and to avoid the expense and inconvenience of overdosage. Some patients need injections of 15 units each week. A few need it oftener than that. Some of our patients are maintained with normal blood levels and with no complications produced by pernicious anemia with injections as infrequently as every four, six or eight weeks.

Dr. Russell L. Haden: If more than 15 units of liver extract is needed monthly we prefer to give a single injection of 30 units. This method works just as well, and the patient likes it better. It is most important to have a periodic check of the blood to determine the efficacy of treatment, as Dr. Murphy has emphasized. The treatment should be so regulated that the red cell count never fails. The first change in the blood if treatment is not complete is an increase in the size of the red cell best indicated by the volume index, so that we follow the volume index closely. The tongue is an excellent indicator also of the completeness of treatment. If the need for liver extract is not completely satisfied the characteristic clean smooth tongue of active disease quickly appears. The condition of the tongue should always be carefully observed. The question was brought up whether the red cell count will rise too high if an excessive amount of liver extract is given. Rarely a patient may have both pernicious anemia and idiopathic polycythemia vera. When liver extract is given during the pernicious anemia phase, the polycythemia vera becomes active and the red cell count becomes very high. We have one such patient under observation now. Dr. Goldstein raises the question of who was responsible for liver therapy. Dr. Osler long ago emphasized that the credit for a discovery in medicine should go to the person who convinced the world and not to the person to whom the idea first occurred. Dr. George Minot and Dr. William Murphy were the discoverers of the value of liver in the treatment of pernicious anemia.

CARONAMIDE AND PENICILLIN

Serum Levels in Human Beings, Following Multiple Doses of the Drugs

MANSON MEADS, M.D.
ROLAND V. LONG, M.D.
SHERMAN H. PACE, M.D.
and
GEORGE T. HARRELL, M.D.
Winston-Salem, N. C.

Numerous attempts have been made to increase the efficacy of penicillin in the treatment of infections by altering the rate of its absorption or excretion. Beyer and his associates have reported that caronamide (4'-carboxyphenylmethanesulfonanilide), though excreted only by the glomeruli, alters the specific renal tubular enzyme system responsible for the excretion of penicillin.[1] The excretion of penicillin is delayed, so that a higher concentration may be maintained in the blood for more prolonged periods. Other investigators have confirmed the original reports on the penicillin-enhancing effect of caronamide and have noted that the drug is relatively nontoxic when administered over short periods of time.[2]

There is difference of opinion concerning the dose of caronamide necessary to maintain an effective concentration of penicillin in the blood. Direct information on the absorption and excretion of caronamide in human beings has been lacking, since practical methods[5] of measuring the concentrations of the drug in the blood and urine have not been available until recently. Furthermore, the effects of the drug have been studied only during short courses or single interval periods of administration. If the drug has a cumulative effect, concentrations in the blood which might lead to dangerous toxic reactions could easily be produced during more prolonged courses.

The following study was undertaken in an effort to compare the effect of different doses of caronamide on the serum levels of penicillin and caronamide in human beings while the drugs were being administered simultaneously during a three day period.

MATERIALS AND METHODS

The 17 subjects used in this study were ambulatory convalescent patients at the North Carolina Baptist Hospital. All were under the age of 60, and none showed evidence of impaired cardiac, renal or hepatic function. The concentrating power of the renal tubules, as measured by the specific gravity of the urine in all patients and by the phenolsulfonphthalein excretion test in 10 patients, was within normal limits. Diet, salt and fluid intake were unrestricted. No medication was given during the test period which might affect the determination of the serum levels of penicillin and caronamide or interfere with the excretion of the drugs.

One hundred thousand units of commercial crystalline penicillin G[3] was given intramuscularly every four hours day and night for seven days. On the second, third and fourth days, caronamide[4] was simultaneously administered orally to 7 patients (group A), in doses of 2 Gm. every four hours day and night, and to 10 patients (5 each in groups B and C), in doses of 4 Gm. every four hours day and night. The intervals were arranged so that the drugs were always given one-half to one hour before meals to insure better absorption of the caronamide. One to three blood samples were taken daily on the first through the fourth days and on the seventh day. In groups A and B the samples were taken four hours after administration of the drugs and in group C two hours after administration. Serum was removed aseptically and stored at —20 C. Determinations of the penicillin and caronamide levels were then carried out by groups to minimize the technical variations.

Penicillin levels were determined by the dilution method. Serums were diluted serially in 0.5 cc. of tryptic digest beef heart broth, and 50,000 to 100,000 organisms from an eighteen to twenty-four hour culture of beta hemolytic streptococci (strain NY 5) were used as a reference inoculum; this inoculum is inhibited by 0.008 unit of penicillin per cubic centimeter, so that a minimum serum level of 0.0156 unit per cubic centimeter (charted as 0.02) can be measured. The tubes were inspected after 18 hours' incubation at 37 C., and in all cases the result was checked by streaking the broth on a segment of a blood agar plate. The end point was considered the tube in which no growth occurred; if a tube showed no visible growth, but a few colonies appeared on the blood agar streak, the value was recorded midway between that tube and the next tube showing no growth.

Levels of caronamide in the serum were determined by the method of Ziegler and Sprague, which utilizes the Evelyn photoelectric colorimeter.[5] Eighty to 90 per cent of the total caronamide is recovered by this procedure, but the amounts of bound and free drug are not differentiated. A small percentage of the colorimetric value is made up of unidentified metabolic products of caronamide.[1c]

RESULTS

Effect of Doses of Two Grams of Caronamide on Penicillin Level Four Hours After Administration (Group A).—The effect of 2 Gm. of caronamide, given orally every four hours, on the level of penicillin in the serum four hours after an intramuscularly administered dose of 100,000 units (group A) is shown in figure 1. The average of all determinations of penicillin in the serum in the group (indicated by a solid line in the chart) was 0.06 unit per cubic centimeter on the first day and 0.09 unit per cubic centimeter on the seventh day—the control periods before and after caronamide therapy, respectively. On the second day of the test—the day simultaneous caronamide and penicillin therapy was begun—the average was 0.1 unit per cubic centimeter; on the two successive days the average was 0.17 and 0.14 unit per cubic centimeter.

Moderate variations in concentrations of penicillin in the serum were observed in individual patients in group A during all phases of the test period. Three out of the 7 patients showed no significant effect from the administration of caronamide at any time; in the remaining 4, intermittent twofold to fourfold increases in the level of penicillin in the serum were observed on six occasions. In these subjects the rises occurred

during the third or fourth days, after two or three days of combined therapy; in 5 of the 6 instances they were followed later in the same day by levels similar to those observed during the control periods before and after caronamide therapy.

Effect of Doses of Four Grams of Caronamide on Penicillin Level Four Hours After Administration (Group B).—The effect of 4 Gm. of caronamide, given orally every four hours, on the level of penicillin in the serum four hours after an intramuscularly administered dose of 100,000 units of penicillin (group B) is shown in figure 2. The average of all determinations of penicillin in the serum in the group was 0.065 unit per cubic centimeter on the first day and 0.04 unit per cubic centimeter on the seventh day. On the second day of the test the average level of penicillin in the serum was 0.063 unit per cubic centimeter; on the two succeeding days the average was 0.25 and 0.26 unit per cubic centimeter.

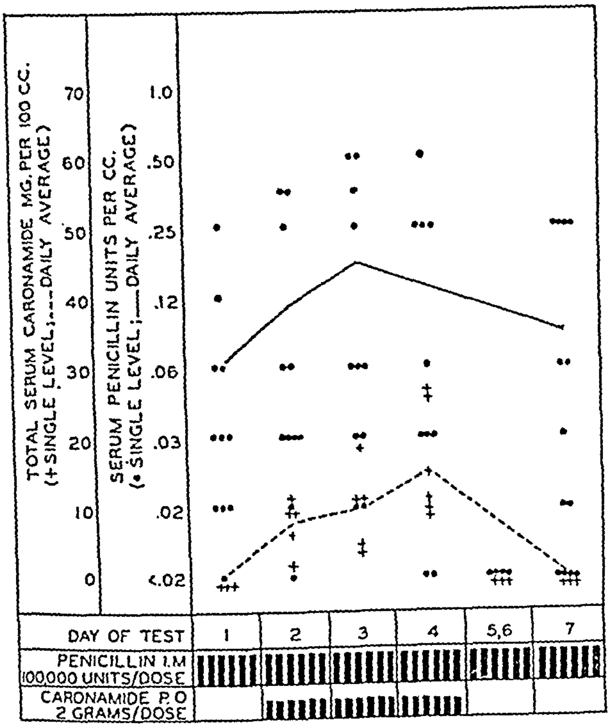

Fig. 1.—Effect of 2 Gm. of caronamide, given orally every four hours, on the serum level of penicillin four hours after an intramuscularly administered dose of 100,000 units of penicillin. (Group A.)

As with the lower dosage of caronamide (group A), variations in penicillin levels in the same patient and between patients in the group during the seven days of observation were moderately wide. Each of the 5 subjects showed at least one significant elevation in the concentration of penicillin in the serum; nine of the twelve significantly increased titers were observed in 2 patients. In these 2 patients the rises in titer were noted on four and five consecutive determinations, respectively, suggesting a sustained elevation in concentration. One of eleven samples taken on the second day showed a twofold rise in penicillin titer. On the third day six of ten samples showed a twofold to fourfold increase, and on the fourth day five of eight samples revealed a twofold to eightfold increase. Samples taken during the test period before the elevations occurred and after they subsided showed levels no greater than those obtained during the control periods before and after caronamide therapy.

Effect of Doses of Four Grams of Caronamide on Penicillin Level Two Hours After Administration (Group C).—The effect of 4 Gm. of caronamide, given orally every four hours, on the levels of penicillin in the serum two hours after an intramuscularly administered dose of 100,000 units of penicillin (group C) is shown in figure 3. The enhancing effect of caronamide on penicillin concentrations is more pronounced at this interval than at four hours. The average of all determinations of penicillin in the serum in the group was 0.08 unit per cubic centimeter on the first day and 0.05 unit per cubic centimeter on the seventh day. On the second day of the test the average level of penicillin in the serum was 0.57 unit per cubic centimeter; on the two succeeding days the average was 1.25 units per cubic centimeter and 1.06 units per cubic centimeter.

The effect of caronamide on penicillin levels two hours after administration was fairly consistent in each subject, but varied widely among the 5 subjects in the group. During the second day of therapy, ten of eleven blood samples showed a threefold to eightfold increase in penicillin concentration. The maximum effect was reached the following day; each of eleven samples had a fourfold to seventeenfold increase. On the fourth day, the penicillin concentration was slightly lower, though nine of ten samples showed a fourfold to thirteenfold rise in titer.

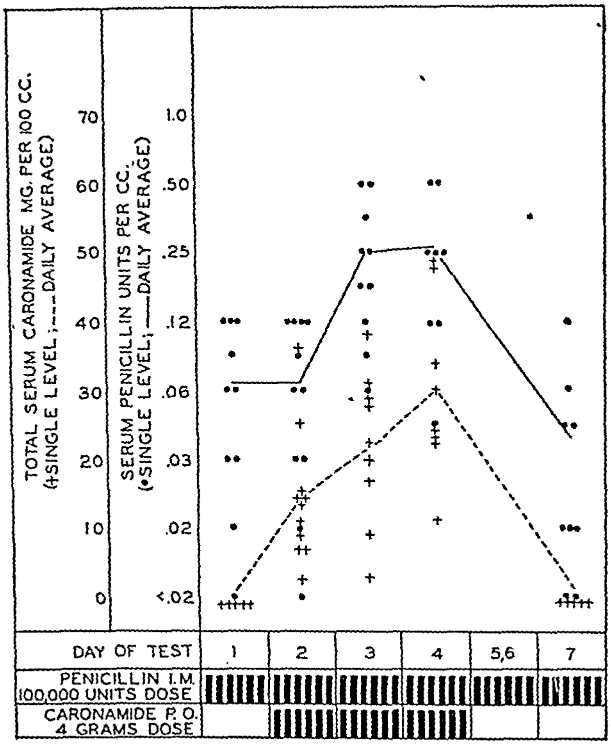

Fig. 2.—Effect of 4 Gm. of caronamide, given orally every four hours, on the serum level of penicillin four hours after an intramuscularly administered dose of 100,000 units of penicillin. (Group B.)

Serum Levels of Caronamide.—The levels of caronamide in the serum in groups A, B and C are plotted on figures 1, 2 and 3, respectively. The trends and variations closely parallel those for penicillin. The average concentrations (indicated by broken lines in the charts) rose progressively during the three days of caronamide therapy in all groups. With a dose of 2 Gm. every four hours, the average levels of caronamide in the serum four hours after administration (group A) were 7.8, 9.5 and 16.1 mg. per hundred cubic centimeters on the second, third and fourth days, respectively. With 4 Gm. every four hours, the levels of caronamide in the serum four hours after administration (group B) averaged 14.0, 21.7 and 30.3 mg. per hundred cubic centimeters on the second, third and fourth days. With a dose of 4 Gm., blood samples taken two hours after administration (group C) on these days showed average caronamide levels of 25.3, 38.6 and 46.2 mg. per hundred cubic centimeters.

The penicillin concentrations reached a peak on the third day and then leveled off. In the great majority of instances, a level of caronamide in the serum of 20 to 25 mg. per hundred cubic centimeters was necessary to produce a twofold rise in penicillin titer. When the blood concentration of caronamide was greater than 30 mg. per hundred cubic centimeters, the penicillin titer almost always showed an increase of fourfold or more.

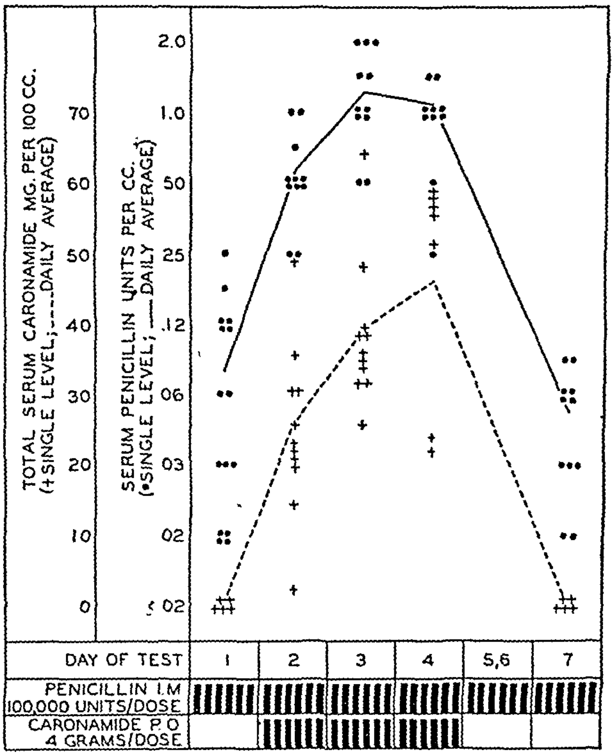

Fig. 3.—Effect of 4 Gm. of caronamide, given orally every four hours, on the serum level of penicillin two hours after an intramuscularly administered dose of 100,000 units of penicillin. (Group C.)

Toxic Manifestations.—Nausea occurred in 3 patients after thirty-six to forty-eight hours of continuous caronamide therapy in doses of 4 Gm. every four hours. In 2 instances the nausea occurred in the early morning and treatment with the drug was discontinued before blood samples were taken. In the third, nausea developed when the caronamide levels four hours after administration of a dose were 47 and 50 mg. per hundred cubic centimeters. Two patients had no complaints with caronamide levels of 50 and 60 mg. per hundred cubic centimeters two hours after administration of a dose. One patient vomited soon after receiving a dose of caronamide.

COMMENT

The results of this study indicate that caronamide has a cumulative effect when administered over a period of three days in doses similar to those which have been used by previous investigators during shorter intervals. The potentially toxic effects of caronamide suggested by these experiments call for a reevaluation of the use of the drug. The benefits achieved by raising the blood levels of penicillin must be balanced against the dangers of administering sufficient caronamide to secure this effect.

Effective Dose of Caronamide.—The enhancing effect of caronamide on the penicillin level in the blood varied not only in relation to the amounts of caronamide given, but also in different patients taking similar amounts of the drug. Multiple observations in 3 of the 7 patients receiving the smaller dose of caronamide revealed effective levels of the drug on only two occasions; these levels occurred in the same patient on the last day of the test and could be attributed to a cumulative effect. In the majority of 10 patients who received the larger dose, effective caronamide levels were present during the entire three day test period. These levels were observed two hours after administration of the drug on all days and four hours after administration on the second and third days. The cumulative effects of caronamide therapy were most apparent in the group receiving the larger dose.

In most instances serum levels of caronamide of 20 to 25 mg. per hundred cubic centimeters were necessary before a twofold increase in concentration of penicillin in the serum was noted. Caronamide levels of 30 mg. or more per hundred cubic centimeters resulted in a fourfold to seventeenfold enhancement of penicillin concentration two to four hours after administration of a dose. These observations are similar to those made in 2 patients by Boger, Kay, Eisman and Yoeman, who observed that 20 to 30 mg. of caronamide per hundred cubic centimeters of serum were required to inhibit the excretion of penicillin by normal renal tubules.[6]

It would, therefore, appear that caronamide levels approximating 30 mg. per hundred cubic centimeters of serum are necessary for an effective increase in levels of penicillin in the serum. Beyer and his associates have observed in dogs that a uniform blood level of caronamide is readily achieved by a large initial dose of the drug, followed by a smaller maintenance dose.[1b] It would appear that a similar dosage schedule is indicated in human beings to maintain an effective serum concentration of caronamide without the dangers of cumulative effects.

Seeler, Wilcox and Finland [2a] observed that relatively low doses of caronamide are effective in enhancing serum levels of penicillin in patients more than 60 years old. They suggest that the decreased tubular mass commonly present in aged persons is responsible for this.

Application to Penicillin Therapy.—In view of the demonstrated effectiveness of caronamide in raising serum levels of penicillin, the drug would appear to be a useful adjunct in the treatment of certain types of infection, provided that its potential dangers are not too great. In most infections caused by penicillin-susceptible organisms effective levels of the antibiotic are readily attained. Whether caronamide will be found to have a place in the treatment of such infections is an economic question that will depend on the eventual cost of caronamide and penicillin. In some infections due to susceptible organisms effective serum levels can not be attained economically with penicillin alone. An example of such an infection would be a localizing abscess, where higher serum levels are necessary to penetrate a relatively avascular or necrotic inflammatory barrier. In such cases caronamide would be useful in achieving serum levels of penicillin not attainable without prohibitively expensive doses of penicillin alone.

---

[6] Boger, W. P.; Kay, C. F.; Eisman, S. H., and Yoeman, E. E.: Caronamide, a Compound That Inhibits Penicillin Excretion by the Renal Tubules, *Applied to the Treatment of Subacute Bacterial Endocarditis,* Am. J. M. Sc. **214**: 493-502 (Nov.) 1947.

Infections due to organisms of low susceptibility or to usually susceptible organisms which have acquired a moderate degree of resistance sometimes respond to high concentration of penicillin in the blood stream. Effective levels can occasionally be achieved by massive doses of penicillin, and this method has been employed in cases of subacute bacterial endocarditis due to relatively resistant strains of organisms. Penicillin alone is a drug of low toxicity, even in massive doses. Additional experiments are necessary before a definite conclusion can be reached as to the value of caronamide given over a long period in such infections. The higher and more effective serum levels of penicillin which could be achieved thereby might decrease the tendency toward the development of drug fastness and shorten the total course of the illness.

Toxicity of Caronamide.—Three of the 17 patients in this study became nauseated, and 1 vomited. Caronamide levels of 47 and 50 mg. per hundred cubic centimeters of serum were present four hours after a dose of 4 Gm. on the third day of treatment in 1 subject with persistent nausea. This symptom disappeared shortly after caronamide therapy was stopped. Unfortunately, treatment with the drug was discontinued before blood samples were obtained from the other 2 patients. This single observation suggests that in some persons the range between effective and toxic serum levels of caronamide may limit the usefulness of the drug. Strauss and his associates observed mild gastrointestinal disturbances in patients who were receiving caronamide, penicillin and sodium benzoate orally over a period of twenty-four hours.[2b] They were unable to determine which drug was responsible for these symptoms.

Evidence of renal damage during the administration of caronamide was observed by Boger and his associates in 1 patient; in view of the time relationship, this damage may have resulted from cumulative caronamide serum levels.[6] This patient was receiving 3 Gm. of caronamide every three hours; on the eighth day of continuous administration, red and white cells appeared in the urine, accompanied with a slight rise in blood urea nitrogen and a decided drop in urea clearance. These abnormalities disappeared within a few days after caronamide therapy was discontinued.

The drug is similar in chemical structure to compounds of the sulfonamide group, which are known to cause toxic effects. Boger records Duncan's observation of a rash which was probably due to caronamide. One of us (G. T. H.) has seen a patient in another hospital who showed red and white cells in the urine, as well as nodules in the skin and subcutaneous tissues, painful hyperemic swelling of the interphalangeal joints and scaling of the skin. These observations suggest that caronamide like the sulfonamide drugs may produce changes similar to periarteritis nodosa.

Animal experiments on the toxicity of caronamide given over long periods are reported by Beyer and his associates.[7] Six dogs received caronamide in oral doses ranging from 0.4 to 1.5 Gm. per kilogram of body weight for a four week period. No consistent effect on the amounts of creatinine, urea and nonprotein nitrogen in the blood or on the content of creatinine, urea nitrogen and total nitrogen in the urine was noted. At the end of the test period no abnormal microscopic changes were observed in renal sections. The experimental conditions were optimal for preventing renal damage and limiting drug accumulation. Young dogs were used; the test diet produced a relatively alkaline urine, and the high fluid intake resulted in a large daily output of urine with a low specific gravity.

Studies on human subjects over short periods of time have revealed no definite symptoms or laboratory observations suggestive of renal damage. Children given caronamide over a period of one or two weeks in daily doses of 0.1 to 0.4 Gm. per kilogram of body weight showed no definite toxic effects.[2a] Longer periods of study in human beings are necessary for final evaluation of the potential toxicity of caronamide.

NEED FOR PHARMACOLOGIC STUDIES IN HUMAN BEINGS

Most studies on caronamide in human beings have been based on a single dose or on the administration of the drug over a period of twenty-four hours or less. Long term studies employing doses of 3 Gm. every three hours or 4 Gm. every four hours, as are being recommended, are urgently needed.

Caution should be urged in the use of the drug pending further evaluation by many investigators. At present it would appear wise to control treatment by testing the caronamide level once or twice a day, two hours after administration of a dose of the drug. In addition, a liberal intake of fluid should be given to maintain an adequate daily output of urine.[8]

SUMMARY AND CONCLUSIONS

Caronamide raises the penicillin concentration in serum when both drugs are administered simultaneously over a period of three days.

Ordinarily a serum level of 25 mg. of caronamide per hundred cubic centimeters is necessary to achieve a twofold increase in penicillin concentration in the serum; caronamide levels exceeding 30 mg. are necessary to increase the penicillin concentration fourfold or more.

Doses of 4 Gm. every four hours are necessary to achieve a caronamide level of 30 mg. per hundred cubic centimeters of serum four hours after the oral administration of the drug.

A cumulative effect was noted with both doses of 2 and 4 Gm. of caronamide given orally every four hours during the three days of continuous treatment. Maximum penicillin levels were achieved after two days of combined treatment

Mild toxic effects were produced by levels of caronamide required to achieve effective enhancement of penicillin concentrations in the serum; other writers have noted severer reactions.

Caronamide should be used with caution until long term pharmacologic studies in human beings are completed. Until this time it is strongly suggested that the blood level of caronamide be followed and adequate urinary output maintained during treatment, particularly in cases in which decreased renal function is suspected.

WHAT IS PSYCHOTHERAPY TO THE INTERNIST?

HENRY M. THOMAS Jr., M.D.
Baltimore

Study and treatment of the patient as a whole implies a psychologic as well as an organic approach and requires the combined endeavor of clinicians and psychiatrists. Many internists carelessly or by design develop a technic which obviates grappling with the patients' psyche. One group emphasizes the importance of the subtle art of physical diagnosis and spotlights the discovery of a faint diastolic murmur or the tip of a palpable spleen, while a second group divert themselves and each other by a complicated study of the chemical dislocations of various syndromes. A third group specializes in every available drug and synthetic preparation, and to this group each symptom or threat of a symptom calls for a therapeutic order. To all of these groups the business of ministering to the psychologic aspects of disease is someone else's obligation. If the patient is neurotic, let him be sent to physicians who specialize in neurosis. I suspect that the physicians in these three groups, and there are other similar groups, unconsciously, at an early stage, began to avoid involvement in the complex and illusive aspects of human nature. They are inept when dealing with personalities and therefore tend to consider psychiatrists unnecessary except for psychotic patients. They inveigh against the tendency to invite psychiatrists in to the study of cases before all organic disease has been eliminated. Some of them think that psychoanalysis is inadequately substantiated. Others believe that analysts, when they delve into the personality structure, using the theoretical concept of symbolism of the unconscious, will find abnormalities in every person which they will attempt to rearrange into a "normal" pattern.

Perhaps I have said enough to give an inkling of the tremendous prejudice I have noticed throughout the medical profession against admitting formal psychologic or psychiatric approach to all medical patients. I shall not belabor the point further nor attempt to defend or condone psychiatry or psychosomatic medicine. What I shall try to do is to clarify the significance of the straws that are blowing past in ever increasing numbers in the stiff breeze of scientific study of the psychologic aspects of organic disease.

In former years the psychology of medicine was learned only by observing how experienced clinicians handled sick human beings. This aspect of the care of patients came to be distrusted in the time of Osler, Shattuck, Delafield and the other leaders of the systematic study of medicine. They became preoccupied with developing and improving accurate diagnosis. The zealous search after etiologic factors, coupled with the discovery that many of the time-honored drugs in the pharmacopeia were inert, inevitably concentrated attention on treatment in those cases in which diagnosis could be substantiated and therapeutic results could be accurately measured. The power of suggestion by placeboes was recognized, but was utilized mainly as a control in studies of drug therapy.

During this period psychiatry, independently, was making great progress, although in most instances it was isolated in mental institutions which were far away from hospitals for medical and surgical cases. As it became apparent that many medical cases had important psychologic aspects as well, the psychiatrists were consulted. Appel,[1] writing about psychiatric therapy, stated:

> When a patient comes to the doctor he is in an attitude of expecting relief not only from his physical symptoms but from his insecurity. It is important for the physician to be aware of this psychological tradition even if he is treating an organic illness, and to use suggestion constructively and not destructively. It is here that the physician's manner and bearing are so important. Indefiniteness, lack of assurance, uncertainty, undue gravity, or silence may be devastating to the patient. Such behavior feeds his imagination and apprehension with all sorts of forebodings. A hasty word or an incomplete explanation may leave the patient with almost unbearable insecurity or fright.

The introduction of psychiatric thinking into medical problems soon uncovered a wide field, the exploration of which has come to be known as psychosomatic medicine. This departure from the orthodox concept of internal medicine has not been easily accepted. It is confused by some with that part of the psychologic approach to patients which seemed to be well handled by our grandfather general practitioners but has been lost sight of by the specialists of today. To others the psychiatric explanation of common symptoms still sounds strange. For instance, Saul[2] discussed hunger pains as follows:

> In the gastric ulcer cases the impulses involved are apparently less various, and consist more specifically of frustrated desires for love, care, dependence and the like. These have become so intimately associated with the functioning of the stomach that cravings for them cause the stomach to behave physiologically just as though they were expecting food.

This is difficult for many physicians to agree to without reservation or to consider as fundamentally important from an etiologic point of view.

With recognition of this strong antagonism to the application of anything even suggestive of a freudian approach to somatic problems there still is much general interest in the rapidly growing mass of evidence which tends to show the functionally intimate interrelationship between psyche and soma, mind and body, the consciousness, on the one hand, and needs, urges, responses to the environment (especially parental behavior) on the other.[2a] As internists we should encourage the correlated studies of emotions and bodily changes, but meanwhile we must recognize that, like it or not, we are implicated in our patient's emotional reactions to disease and must apply ourselves to this problem. Before the days of Lister it was no mistake to put dirty hands into a wound. Today such a blunder would not be countenanced by a trained nurse or medical student. Today we must avoid comparable breaks in technic of psychotherapy.

ILLUSTRATIVE CASES

The following cases illustrate breaks in technic which happen every day. The physician, as Kanner[3] said, "means no harm."

CASE 1.—A 27 year old man had been known to have congenital cardiac disease from infancy. His parents, with good medical advice, had brought him up to take part in all games

---

Read before the Section on Internal Medicine at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

and athletic activities that his associates indulged in, and he had played on his high school baseball team. After college he had gone into farming, with hunting long hours in field and forest as his major relaxation. From time to time he had been carefully examined and always had accepted the advice for moderate caution that wise physicians had given him. Recently, he had grippe with high temperature, tachycardia, headache and general malaise. The local physician was called and treated him. Two days later, his temperature having fallen to normal and his general condition having become greatly improved, the local physician casually said to the patient, "I surely am glad you are better. I never saw a worse heart than yours was two days ago." From that time on he became heart conscious, aware of extrasystoles and bothered by faintness and palpitation. He limited his activities and lost much of his former *joie de vivre*. His local physician had planted ineradicably the seeds of worry and fear in this courageous young man's imagination and, in fact, changed his entire life.

Case 2.—A woman of 44 consulted a physician for a minor ailment. During the checkover her blood pressure was observed to be 220 systolic and 130 diastolic. The physician clearly showed his amazement by his questioning of the patient when he said, "Don't you ever have severe headaches? Aren't you conscious of your heart pounding? Don't you ever get dizzy? Don't you ever get short of breath?" And finally, "Well, you certainly should have some or all of those symptoms with that blood pressure." From then on she became anxious about her health for the first time, and began to experience some of the symptoms her physician had called to her attention.

Comment.—In these 2 cases the symptoms became apparent to the patient directly following ill considered remarks of the physician which resulted in anxious concern and depression. The power that even their lightly spoken words have to instil fear into the minds of patients often is overlooked by physicians. A veritable chain reaction may be set in motion. To an imaginative timid person high blood pressure quickly leads to thoughts of apoplexy, paralysis and death. A cardiac murmur means heart trouble and impending sudden death. In this day of popular medical education in magazines and newspapers, the man on the street always has preconceived notions of cause and effect and of the dangers of most diseases. Therefore, it becomes necessary for the physician to be aware of all the little or big ideas that may act as entering wedges for fear into the patient's consciousness and avoid them or neutralize them on the spot. If the physical examination is discussed in the presence of the patient, abnormalities should be described in technical terms and should be cleared of alarming implications. We all see patients who tell us, "three doctors have warned me that I might have a stroke any minute" or "two doctors have said I might have a sudden heart attack." Actually what these doctors probably told their patients was that they did have some elevation of blood pressure or that there was something wrong with their hearts. What they did not see was the importance of convincing the patient that these conditions in most instances have little or no immediate danger and that what danger they hold may not be encountered for a long time or possibly not until the end of a normal span of years.

The following brief case history illustrates the gravity of misinterpreting the functional aspects of a case.

Case 3.—A 43 year old man was admitted with the complaint of a gastric ulcer, from which he was supposed to have had hemorrhages within the past two weeks. A year previously, on consulting a physician, he complained of hunger pains and acid eructation. He was told that he had ulcers and was put to bed for four weeks, limited to a milk and cream diet and given blunting powders. For a year thereafter he was kept on a meat-free soft diet, with greatly restricted activities, which precluded work. During this time he lost 25 pounds (11 Kg.). On admission to the hospital he refused to take anything but liquids and lay on his bed deeply depressed and constant in his complaints of abdominal pain. On several occasions he insisted that he had spit up blood from his stomach, although examination of gastric contents and six examinations of the stool, showed no blood. Roentgen and fluoroscopic examination did not reveal any organic lesion or scar, although pylorospasm and hyperacidity were present.

Comment.—The handling of this case demonstrates several of the most distressing results of breaks in therapeutic technic. The treatment itself convinced the patient of the alarming seriousness of the lesion in the stomach, which was a completely erroneous impression. The illness was permitted to drag on with ever increasing fixation of the conditioned invalidism, and the underlying nervous instability received no direct or indirect therapeutic consideration.

PSYCHOLOGIC FACTORS IN ORGANIC DISEASE

In order to avoid contributing to patients' anxiety over their illness and to allay their symptom-producing fears, one must be conversant with the mental aspects of numerous medical conditions. Many of these were brought into sharp focus during World War II. Neurocirculatory asthenia is no longer considered primarily cardiovascular in origin. Mucous colitis is more a symptom than a disease. Gastric ulcer is coming to be regarded by many as an organic complication of an underlying neurosis [4]; cardiospasm and pylorospasm are of the same type. The important possibility of a major role being played by psychic disorders in the causation of certain types of hypertension and of exophthalmic goiter [5] is recognized. Angina pectoris, allergic diseases, many forms of dermatitis, migraine, glaucoma and obesity—all are now known to be tremendously aggravated by nervous tension and anxiety. Too little attention has been paid to worry, anxiety and depression engendered by disease itself, since the best treatment of these mental states is the prompt and efficient correction of the underlying disease.

Although many able physicians make no effort to understand the psychologic implications of organic disease, some of the more sensitive ones tend to "soften the blow" too much, even to the point of deceiving the patient or of putting off important treatment for fear of alarming the patient. There are doctors who regularly tell their patients that their blood pressure is lower than it actually is. A little thought would show these physicians that their patients will see other doctors and that all doctors cannot hope to dissemble equally. It is far better to teach the patient that daily or hourly fluctuations in blood pressure may be so great that there is little significance in any single reading [6] and that therefore he is better off not knowing what it is.

LITERATURE

Internists will be interested in reading some of the excellent recent books on psychotherapy, such as the works of Levine,[7] Strecker and Ebaugh [8] and Oscar Diethelm.[9] He should be familiar with the Minnesota experiment described by Smith.[10] An extremely interesting collection of contributions by forty psychiatrists, psychologists and internists interested in psychosomatic medicine is to be found in the two volume work edited by Hunt.[11] Dunbar's book[12] summarizes the field of psychosomatic medicine. Internists should not avoid some of the books written primarily for pediatricians, since the end results of behavior problems in childhood often are encountered in adult patients. One such book was written by Isaacs,[13] and a book that no one should miss is one by Kanner.[3]

The step from avoiding harmful malapropisms or destructive suggestions to making actual psychotherapeutic contributions and using suggestion constructively is not difficult. The psychologic aspects of every case should not be abandoned to psychiatrists, since internists are in better position to provide authoritative reassurance concerning the whole disease picture. Search for organic lesions must not be discontinued when psychotherapy is brought into the picture, because we all have seen cases in which neurotic symptoms have obscured serious organic disease.

HELPFUL TECHNICS

A simple method most medical practitioners find themselves using is a combination of suggestion and reasoning which is reinforced by their prestige and positive assertion. If the patient is to be helped he must be convinced by adequate explanation of the anatomic, physiologic and mental aspects of his case even though the explanation is tedious, time consuming and, often, difficult. It is improper to threaten the patient with dire results unless he obeys instructions, since this method is motivated by fear rather than reassurance.

Reassurance must be based on truth, since a structure built of falsehoods breaks down soon or late. Cabot[14] felt very strongly on this point. However, we must constantly remind ourselves that what appears to be the truth of medical explanation today may be far from the truth tomorrow. Also, the words we utter as a true statement may be interpreted by the patient to mean something entirely different. There can be no sure way of reaching or imparting a durable absolute truth. Therefore, we should be careful not to force on an unwilling patient disagreeable or alarming statements which we think are true. Gentle probing into the patient's attitude and wishes will reveal the correct course to pursue in his particular case and how much definite information he needs and really desires. Hope need never be completely destroyed even though false hope should be removed lest patients with irreversible lesions continue a futile quest for unattainable cure.

It is impossible to overemphasize the value of hope to the patient. Hopefulness developed through a true understanding of the symptoms can be translated into a desire for and an effort toward improvement.[15] Solomon knew the importance of this when he said in the Book of Proverbs, "Hope deferred maketh the heart sick: but when the desire cometh, it is a tree of life."

An ill timed effort at humor may infuriate or wound the patient, yet the physician's sense of humor is a magnificent therapeutic instrument. Unfortunately, psychiatric instruction gives us little or no help in its use. If the doctor can find a neutral object about which he and the patient can laugh, then the tension is lessened and a sense of friendliness and common purpose established. The introduction of humor must not conflict with the serious and thorough consideration of the patient's complaints. We may not be too casual on the one hand or too much concerned on the other. The only sure way of reaching the proper attitude is to understand the patient's thoughts and anxiety reactions and to watch very closely the nature of his responses with a sensitive appreciation of what persons usually worry about in the particular situation.

SUMMARY

Psychotherapy is treatment of the patient through his mind. I have not attempted to describe current technics used by psychiatrists. My purpose has been to justify psychotherapy as an integral part of every contact with patients and to indicate each physician's obligation to participate. This can be accomplished efficaciously only by keen awareness of accepted psychosomatic and psychiatric concepts and by a well integrated approach to the human being who is ill.

ABSTRACT OF DISCUSSION

Dr. Francis J. Gerty, Chicago: Dr. Thomas is to be congratulated on his valiant effort to attempt to tell you what psychotherapy is. A great many things have been called psychotherapy, and a great many things that have been psychotherapy have been called something else. Many years ago when I was a resident, an eminent neuropsychiatrist used to call on me to take his practice when he went on vacation. This man was successful in treating patients with functional disorders. He did not believe much in psychotherapy, beyond the fact that the physician should be a man of character and be honest with his patient. He did believe that psychoneurotic patients needed a sedative, a tonic and an increase in the supply of iodine sometimes, so he had a certain sedative mixture to which the druggist appended his name. He gave them sodium cacodylate by mouth. When he died, people in his office used to send his patients to me; I lost all of them, because his remedies did not work with me. The patients came to the conclusion that this man had had some secret formula and that that had died with him. The secret ingredient was the man, and this is an ingredient in all psychotherapy. We can apply the term "psychotherapy" to a great many things—placebo, bedside manner, reassurance, suggestion, hypnosis and psychoanalysis—but all of this is not very helpful when we attempt to make psychotherapy useful in our practice. We must look on psychotherapy, or at least psychotherapists, much as we look on the other remedies, as far as testing them out and weighing them are concerned. We are just beginning to look at psychotherapy this way. We are trying to examine honestly what elements enter into the matter of psychotherapy. There is an unconscious factor in psychotherapy which must be studied and of which we must become much more conscious. It is more important that the physician remove these in himself than that he set about removing them in the patient. This means that he must have a definite feeling for his patient; the patient will reciprocate with feeling on his part, and with this mutual feeling psychotherapy can be carried forward intelligently.

Dr. Thomas: I believe that the two points that have impressed me most in considering this general subject are: First, the psychologic aspects of treatment of the patient should always be present in the physician's mind, and, second, we must not allow our approach to the patient's psyche to remain amateurish, but by reading and thinking about it we must develop a superior type of psychotherapy which has its foundations on sound internal medicine.

EVALUATION OF CANCER CONTROL METHODS IN CONNECTICUT

MATTHEW H. GRISWOLD, M.D.
Hartford, Conn.

Analysis of the first total tables from the record registry in Connecticut enables one to evaluate cancer control methods for the past twelve years. The sources of factual information are the death rates, the attendance of patients with cancer at the clinics or general hospitals, the intervals of delay between symptoms and treatment and the attendance of physicians in the mutual educational program.

The age-adjusted cancer death rates are shown in table 1.[1]

The age-adjusted male cancer death rate has risen during the twelve year period, but appears to be leveling. The female age-adjusted cancer death rate has fallen. Since the average duration of life of all cancer patients is two years from the onset of the disease, the mortality rates of any year actually are a measure of events of two years before a retroactive index of progress. With this thought in mind, the gradual leveling of the total age-adjusted mortality rates in Connecticut is an encouraging sign.

The incidence rate of cancer as recorded in the record registry has increased with consistency, as shown in table 2.

The increase in the incidence rates as demonstrated in this table reflects the improvement in services rendered to persons in this state by every new measure introduced to increase the understanding of cancer. Within two years of the establishment of the division for cancer in the State Department of Health, a remarkable increase in hospital and clinic attendance of persons with cancer was noted. The publicity attendant on and the effort made by this new unit was undoubtedly responsible for this. In 1938, with the active organization of the Association of Connecticut Tumor Clinics and the attendant establishment of new clinics, another big increase in recognized treated cancer occurred. In 1941, the distribution of state funds to each of the general hospitals, the systematic backtracking of all cancer from 1935, the development of the state record registry and the establishment of universal follow-up of all cancer patients through the Division of Cancer and Other Chronic Diseases resulted in a dramatic increase in recognized treated cancer. In 1944, with the first successful drive of the Connecticut Cancer Society on a statewide basis, another increase occurred in recorded new cases of cancer. In 1946, with the inauguration by the Division of Cancer and Other Chronic Diseases of the popular and instructive Mutual Education Program, whereby four times a year three physicians from each general hospital visit another general hospital in the state and attend its cancer clinic, another increase in recognized cancer occurred. It was felt from an evaluation of the results on the records in the record registry that the general level of medical service was high in this state and that, by sharing, the whole level could be raised more quickly than by any other method. The token remuneration and expenses paid to each visiting physicians are furnished through the State Department of Health. All of these improvements have been made by the consistent effort to expand existing facilities to adequacy in the most universal and least disruptive way and with as little additional expense as possible.

The total incidence rates suggest but do not give sufficient detail to make clear the extent to which this voluntary registry of cancer has become adequate for obtaining the true picture of cancer morbidity. Checks with the death records and contacts with surrounding states and famous medical clinics make it possible for nearly every case of cancer to be known to this registry. Hospital insurance held by an estimated 40 per cent of the population of the state has encouraged the ready use of these facilities even by some persons who might not actually need hospital care. It is realized that cases of cancer of the skin treated in physician's offices are missed. Despite this, 9.5 per cent of cancer reported to this registry is cancer of the skin. Table 3 gives the incidence rates per 100,000 population in Connecticut by site and sex for the year 1945. This gives a clear picture of the size of the problem as it pertains to new cases.

TABLE 1.—*Age and Sex Adjusted Mortality Rate*

Connecticut 1935-1946, per 100,000

	Mortality Rate		
Year	Male Patients	Female Patients	Total
1935	102.9	120.3	111.6
1936	103.7	115.3	109.3
1937	101.2	114.0	107.3
1938	113.7	117.1	114.9
1939	108.6	116.8	112.3
1940	117.9	119.7	118.3
1941	115.6	120.2	117.6
1942	116.4	121.0	118.0
1943	113.8	121.9	118.4
1944	111.5	124.5	118.5
1945	120.7	119.2	118.9
1946	118.6	119.6	119.1

TABLE 2.—*Incidence Rates for Cancer*

Connecticut 1935-1946, per 100,000

	Incidence Rates	
Year	Male Patients	Female Patients
1935	114.5	145.9
1936	123.8	145.8
1937	127.4	166.3
1938	142.1	172.2
1939	162.4	193.1
1940	167.3	183.9
1941	179.8	207.2
1942	190.9	215.8
1943	194.9	229.1
1944	217.0	251.1
1945	229.4	259.5
1946	254.2	260.6

A follow-up over a long period of time is a requirement if accurate appraisal is to be attempted in studying cancer control methods, since the end results of cancer cannot be obtained until years after the onset of the original lesion. The staff of the Division of Cancer and other Chronic Diseases has trained new workers and guided experienced ones in hospital after hospital in the technics of obtaining follow-up.[2] Since over half of all cases recorded in the registry are private cases, ingenious and tactful procedures had to be evolved to reach this frequently unfollowed group. It was found when the system of follow-up was finally general that over 1,500 patients treated for cancer from 1935 through 1940 had had no follow-up from the time of the discharge after initial treatment. Since that time, the proportion of untraced cases has been so small that

[2] Griswold, M. H., and Macdonald, E. J.: Cancer Record Registry—How It Functions, Connecticut M. J. **11:** 344 (May) 1947.

there are fewer than 5 per cent of the nearly 38,000 cases in the registry lost to follow-up.

From January 1935 through December 1946, in this state of less than 2,000,000 population, there have been 37,863 persons with cancer treated and diagnosed for the first time, for whom there are records in the local hospital cancer record registry and in the state total cancer record registry. There are more females than males in Connecticut, especially in the older age groups. There are, therefore, more cases of some sites of cancer among females than would occur if the sex ratio were even. The Connecticut registry uses as an origin the appearance at the hospital or clinic because normally, if a diagnosis of cancer is made or suspected, the patient is admitted for treatment either simultaneously or within a few days.

TABLE 3.—*Incidence Rates for Cancer by Site by Sex**

1945, per 100,000

* The nomenclature used is the nomenclature of diagnoses of the Memorial Hospital for the treatment of cancer and allied diseases, New York.

The percentage of male and female patients treated within one month, four months and six months of first symptoms is shown in table 4.

About one fifth of both male and female patients over the entire period have been treated within one month of first symptoms. About 40 per cent of both groups are treated within four months of first symptoms, and about half are treated within six months of first symptoms.

The survival rates are the criteria of measurement used[3] in discussions of the over-all cancer picture in this registry. For each of the sites as it is studied separately, a clinical check within weeks of presentation of the study will be sought of all patients living, to determine with reasonable accuracy the rate of cure as well as the survival rate. A patient not checked clinically within twelve months of any report of this registry is considered untraced. In order for a patient to be declared cured, however, an immediate check of each case is a necessity; so many factors alter the accurate description of cures and survivals. The age of the patient is so high at the time of onset and treatment that frequently death from other causes precludes determination of the results of cancer therapy. The average age at the time of treatment in Connecticut for the total period for female patients is 55.4 years and for male patients 59.6 years. Buried in this average is a wide and surprising range of years at the time of treatment according to the site of cancer and sex. Table 5 gives the average age at the time of treatment by selected sites of cancer.

---

[3] Macdonald, E. J.: Survival Rates of Individuals Who Have Had Proved Cancer in Connecticut—1935-1942, Connecticut Health Bull. 58:2 (Nov.) 1944.

The proportionate age distribution by sex for total cancer is given in table 6. Comparable proportions are given by sex for those persons living as of April 1947. Among male patients 29.6 per cent of the total were between 60 and 69 years of age at the time of treatment, 19.9 per cent were between 70 and 79 and 4.7 per cent were over 80. Among female patients, 23.8 per cent were 60 to 69 years of age, 12.6 per cent were from 70 to 79 and 2.7 per cent were over 80 at the time of treatment. The survival rates among male patients are lower than among female patients. When it is observed that one fourth of all male patients in the registry came for treatment or diagnosis after the age of 70, one extremely important probable cause for a shorter period of survival becomes apparent. Another 29.6 per cent were between 60 and 69 at the time of treatment or diagnosis.

Table 4.—*Percentage of Cancer Patients Receiving Treatment Within One, Four and Six Months of First Symptoms*

	Percentage of Patients					
	One Month		Four Months		Six Months	
Year	Male	Female	Male	Female	Male	Female
1935	19.1	18.4	38.1	39.5	47.0	50.3

Total	59.6	55.4

Comparison of the totals of the average age at the time of treatment and the percentage distribution of male and female patients living as of April 1947 shows the living as slightly younger, but without as great a difference as was expected.

One of the most encouraging features of a functioning registry which includes active follow-up of all living patients is the knowledge of the large number of persons who have survived treatment for cancer for more than five years. In Connecticut, there are over 3,000 living five to twelve years after treatment. Expressed another way, there are 174.5 persons out of every 100,000 in the population who have survived treatment for cancer for more than five years—128.9 per 100,000 males and 220.1 per 100,000 females. Also living in Connecticut are 9,000 other persons who have been treated for cancer within the last five years. Each passing year a larger number and a larger percentage of the total reach the five year survival mark, which often means safety.

Over the twelve year period under study, the total cancers have been grouped by site and by sex to determine the percentages of cancer of accessible sites in their relative proportion to the whole series. Table 7 gives the percentage distribution by sex and by site of certain cancers normally considered accessible.

One third of the cancers among male and two thirds among female patients are accessible. To the improvement of the prognosis of these types of cancer every educational effort should be bent. A recent study[4] measuring changing reasons for delay by certain sites of cancer between 1938 and 1946 shows that this effort is being made and is making measurable progress.

It is apparent that the greatest increase in those that come for treatment as soon as they notice symptoms has been among persons with cancer of the respiratory tract, the skin, rectum, buccal cavity and stomach, in that order.

The greatest improvement in the adequacy of medical advice has been among patients with cancers of the breast, stomach, other digestive organs and genitourinary system. The reduction in delay due to negligence and ignorance has been most pronounced in persons with cancers of the rectum, genitourinary system, other digestive organs (table 8, item 5) and respiratory tract, in that order. An increase in 1946 is noted, however, in delay due to negligence on the part of patients with cancer of the skin.

Table 6.—*Percentage Distribution of Cancer by Age and Sex*

1935-1946

Age Groups	Total Male Patients	Male Patients Living as of 1947	Total Female Patients	Female Patients Living as of 1947

Skin	2.1	20.2	5.5	2.1	39.4	51.2	94	94
All others	10.6	44.7	13.8	3.2	31.9	19.1	94	94

Table 9.—*Percentage Distribution of Cancer of Selected Sites*

1935-1946

Site	Percentage Distribution	
	Male	Female
Viscera of the chest cavity	9.1	1.9
Abdominal cavity viscera (excluding rectum and anus)	27.13	18.93
Total	36.23	20.83

There has been a decided increase in diagnosed cancer in both these groups since 1935. This has been more apparent since 1940. Among male patients, there has been an average of 18.7 cases of cancer of the thoracic cavity viscera for each of the seven years from 1940 through 1946. The actual incidence rate for 1945 was 26.4 per 100,000 males. The incidence rate for males for cancer of the abdominal cavity viscera, exclusive of the rectum and anus, averaged 51.0 per 100,000 for seven years and actually was 57.1 per 100,000 for 1945. Among females in the same group, the average incidence rate for seven years was 42.3 per 100,000 while the actual incidence rate for 1945 was 52.4 per 100,000.

The increase or decrease in the other sites of cancer is shown in table 10. The increase is pronounced in cancer of the skin among male patients. It is more gradual in cancer of the rectum and cancer of the male genital and urinary tracts. It is interesting to notice that the rates for cancer of the skeletal system, the upper respiratory tract, the anus and the central nervous system are stationary or beginning to decline. Among female patients, the same thing has happened in cancer of the soft parts, the central nervous system and the anus and metastatic cancer with no primary site discovered. This last observation is particularly encouraging and appears to be consistent year after year. The over-all incidence rates for cancer show an increase of 35.0 per 100,000 among males and 38.3 per 100,000 among females between the seven year average and the 1945 actual experience.

To know the size of the problem, to have an established follow-up system, to have available diagnostic and therapeutic resources, to have an alert medical profession and an aroused laity and to have a division of cancer control capable of tabulating and analyzing these factors are all prerequisites to the final evaluation, which is measured in lives saved, in improving the rate of survival. Table 11 shows the distribution of traced living patients, microscopically proved to have had cancer, alive at yearly intervals following treatment.

Improved preoperative and postoperative care, progressing medical skill in therapeutic technics, reduction in delay on the part of the patient and the physician and cooperation on an almost universal scale have implemented the formation of this record registry. In each year there is improvement in the percentage of survival. This may not be accounted for by the normal increase in the expectation of life of the over-all population, because the progressive increase in age at the time of treatment has been constant, thus absorbing this variable of over-all increased survival as has the five year average difference in age at the time of treatment for those that died within five years and those that survived. From 1935 through 1941, each of the years up to five years following treatment shows steady, and in some instances spectacular, improvement. In the years from 1941 through 1945, the improvement is so pronounced that the promise of an increased five or more year survival rate will be maintained.

Table 10.—*Incidence of Cancer by Selected Sites*

Rate per 100,000

Site	Incidence of Cancer			
	Male		Female	
	7 Year Average	1945	7 Year Average	1945

Clinical Notes, Suggestions and New Instruments

ROCKY MOUNTAIN SPOTTED FEVER TREATED WITH AUREOMYCIN

CRISPIN COOKE, M.D.
Huntington, N. Y.

The occurrence of Rocky Mountain spotted fever due to infection with Rickettsia rickettsi in the eastern part of Long Island, N. Y., is not infrequent, because of the prevalence of the common vector Dermacentor variabilis, the dog tick. There are usually 10 to 15 cases each year in Suffolk County. The mortality of the disease is known to vary from year to year and in different parts of the country from 15 per cent to as high as 37.5 per cent in the Bitter Root Valley.

The following case is reported because of the striking and rapid result obtained with aureomycin, a new antibiotic which has been found to be extremely effective both in vitro and in vivo against rickettsial organisms of several varieties, as well as against certain viruses and bacteria. Aureomycin has been produced from a strain of Streptomyces aureofaciens isolated by Dr. B. M. Duggar of the Lederle Laboratories.

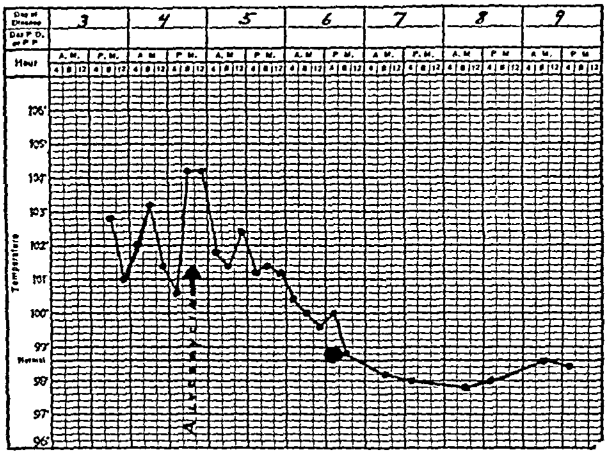
REPORT OF A CASE

A 28 year old white woman was admitted to the Huntington Hospital on July 19, 1948, with a three day history of severe headache, malaise and backache of rather sudden onset. There had been chills and temperature from 101 to 103 F., occasional nausea and vomiting and considerable photophobia. On the morning of admission she had noted a rash on her arms and legs. In the preceding two weeks she had found two or three embedded ticks on her body, the last about six days before onset of the illness. There had been no known exposure to possibly contaminated food or water, and there was no evidence of rat or louse infestation of her surroundings. The past history was entirely noncontributory.

Physical examination showed an acutely ill woman with a temperature of 103 F., pulse rate 120 and respirations 20. Diffusely distributed on the arms and legs there was a discrete pink macular rash, the lesions averaging 1 cm. in diameter. There were only a few on the trunk. The spleen was not palpable, and the results of the rest of the examination were entirely within normal limits. Initial laboratory work revealed a red blood cell count of 4,300,000, hemoglobin 12 Gm. and white blood cell count 8,500, with 75 neutrophils, 22 lymphocytes and 3 mononuclear cells. The urine was normal.

Rocky Mountain spotted fever was considered the most probable diagnosis, but, pending the result of blood culture to rule out meningococcemia, penicillin was given in doses of 300,000 units every six hours for three doses and then discontinued when the culture was reported to be negative. Through Dr. Yale Kneeland at Presbyterian Hospital, we were able to obtain a supply of aureomycin from Dr. Herald Cox of the Lederle Laboratories. Treatment with this was begun twenty-four hours after the patient's admission, on the fourth day of the illness, at which time the rash was more pronounced and violaceous and the temperature was spiking to 104 F. The dosage was 1 Gm. every six hours by mouth for forty-eight hours, at which time the temperature had returned to normal and the patient was dramatically relieved of all her symptoms. The aureomycin dosage was reduced to 0.5 Gm. every six hours for the ensuing twenty-four hours, making a total dose of 10 Gm. There were no symptoms or signs of toxicity, with the possible exception of mild nausea and vomiting for a few hours on the second day of treatment, which was transitory and probably due to other factors since it disappeared in spite of continued use of the drug. The patient continued to improve and was ambulatory, with the rash gone by the ninth day of the illness, and she was discharged from the hospital on the tenth day.

During her course two blood cultures were negative; urine and stool cultures revealed no pathogens. The blood cell count remained normal throughout. The Wassermann reaction of the blood was negative; nonprotein nitrogen was 39 mg. per hundred cubic centimeters, total protein 7.7, albumin 3.4 and globulin 4.3 mg. Serologic studies on the fourth day of the disease showed a negative Widal reaction, negative reaction to the complement fixation test for Rocky Mountain spotted fever and rickettsialpox, agglutination of Proteus OX19 to 1:40 and negative results with OX2 and OXK. On the tenth day, however, the reaction to the complement fixation test was positive for Rocky Mountain spotted fever in a titer of 88. This was confirmed by Dr. Cox at the Lederle Laboratories, who reported a positive result for Rocky Mountain spotted fever in serum dilution up to 1:64. The reaction to the rickettsialpox complement fixation test, which has been found to be somewhat more sensitive in detection of spotted fever early in the disease, also became positive by the tenth day, though in somewhat lower titer.



Temperature chart from the case reported.

COMMENT

It is felt that the prompt response to aureomycin therapy in this confirmed case of spotted fever, in which one would expect a severe febrile course of two to three weeks, is further evidence of the efficacy of this agent against the Rickettsia of Rocky Mountain spotted fever.

A SAFE DIAGNOSTIC OPTICAL ESOPHAGOSCOPE

RUDOLF SCHINDLER, M.D.
Los Angeles

For a long time internists and surgeons have desired to possess an instrument with which the esophagus might be inspected safely and clearly. Esophagitis, a frequent cause of distress (Winkelstein), can be diagnosed only by direct inspection of the inflamed mucosa. Early carcinoma of the esophagus easily escapes roentgenologic detection.

DISADVANTAGES OF ESOPHAGOSCOPES NOW IN USE

The present esophagoscopes are not safe. Mastery of their use requires long study, but even in the hands of the most expert examiner occasional mishaps occur. The most frequent lesion is a hypopharyngeal tear, often leading to mediastinitis and death. Usually it is assumed that esophagoscopy has a morbidity rate of 2 per cent and a mortality rate of 0.5 per cent. These figures would rise considerably if esophagoscopy were to be done by any other than trained experts. The existing dangers attending esophagoscopic examination often prevent the most conscientious physicians from referring their patients for esophagoscopic study. Many esophagoscopists have also felt the need for diminishing the danger of esophagoscopic examination.

A tear of the hypopharynx is almost unknown following gastroscopy. Many thousands of gastroscopies have been done

---

Fellow of the American College of Physicians.

From the Department of Medicine, College of Medical Evangelists, Los Angeles.

by me and most other gastroscopists without any such untoward result. Only rarely is it reported as a curiosity. This is not only true of the present day flexible gastroscope, but it was true also in the days of the rigid gastroscopes. Hübner,[1] in a study on the dangers of gastroscopy in the time of the rigid gastroscope, stated that practically all accidents involved the thoracic esophagus, but no hypopharyngeal lesions occurred.

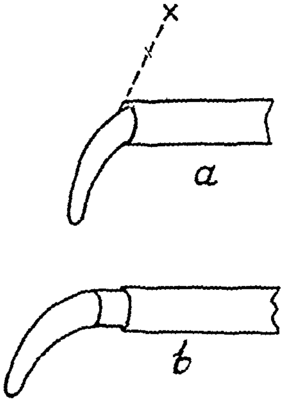

Fig. 1.—Comparison of obturator tips: *a*, faulty, and *b*, correct construction of tip of obturator, with *x* indicating the free dangerous edge.

This astonishing difference between esophagoscopy and gastroscopy is chiefly due to the different principle of introduction used in the two procedures. The introduction of the esophagoscope is done under guidance of the eye, the instrument being an open tube. The introduction of the gastroscope, the rigid as well as the flexible, was and is done under the guidance of the tactile sense, the instrument being equipped with an obturator. Esophagoscopists have contended that lesions could not occur if the esophageal lumen were constantly visualized. They warned[2] that one should never advance the instrument and especially that one should never pass the constrictor muscle of the pharynx if the lumen was not plainly visible. But in spite of these precautions, accidents have continued to happen.

The reason becomes obvious by a simple anatomic consideration. Nobody has ever suggested that one introduce a proctoscope as an open tube under visual guidance. If it were tried, lesions of the sphincteric portion of the rectum would occur, for it is closed by a strong sphincter muscle. It can be opened slightly if the patient is asked to press, but this opening usually is insufficient and may disappear at any moment. Disengagement of the walls of this canal by the use of an obturator is, however, simple.

The conditions at the entrance to the esophagus, though not identical, are similar. There, also, a powerful sphincter muscle is present. It is more frequently open than the anal sphincter muscle, yet it often is tightly closed. It may open after a swallowing movement, and therefore it has been recommended that the open esophagoscope be passed as the patient makes a swallowing movement. But this opening may be of very short duration only; it is easily missed, and it may be absent in apprehensive and spastic patients. Then a slight movement of the open instrument will produce the dreaded lesion.

An instrument bearing a soft rubber obturator may encounter three different situations: (1) The constrictor muscle of the pharynx may be open; then the instrument will enter the esophagus without resistance. (2) The muscle may be closed, but not spastically; then the rubber obturator will take over the function of the metal obturator of the proctoscope, it will gently and without danger disengage the walls and permit the metal tube to follow. (3) The muscle is spastically closed, in which circumstance no instrument can be introduced and its relaxation must be awaited. A rubber obturator, even under pressure, will bend but will not produce a tear. In the first and second instances an open tube is dangerous, a tube closed with a flexible obturator is safe, as ten thousands of examinations with the rigid gastroscope have proved.

It must be admitted that in times past mishaps occurred when esophagoscopes carrying an obturator were used. The reason for these mishaps is apparent. It was the size of these old tubes which was responsible for the accidents. At the entrance of the esophagus an anteroposterior diameter of about 15 mm. can rarely be exceeded. Instruments of times past had this maximum diameter. But in spastic and restless patients the very size of the instrument became dangerous. Esophagoscopists, therefore, reduced the size, and the present day standard Jackson esophagoscope has an outer diameter of only 10 to 13 mm. The rigid Schindler gastroscope of 1922 had a diameter of 11 mm., and no pharyngeal lesions were observed with this instrument.

These facts have been known to many observers. Henning[3] constructed a closed esophagoscope in 1932. Boros[4] in 1947 described an open esophagoscope the lower end of which is a flexible metal spiral. It is to be introduced blindly and probably often can be introduced easily, but if the visual introduction is abandoned the retention of an open tube appears illogical and unnecessary. In fact, each open esophagoscope can be changed into a safe instrument by inserting a tightly fitting rubber obturator.[5] A precaution must be used, however, in such a simple construction. If a rubber obturator bends, an empty space will form between the obturator and the free edge of the metal tube. This free edge then would be a source of danger again. This is avoided by attaching the rubber finger on a metal rod which is a few mm. longer than the esophagoscope (fig. 1).

Thus it is easy to solve the problem of a safe inspection of the esophagus, although such an instrument must not be used if lesions immediately below the constrictor muscle of the pharynx have been recognized at roentgen examination. There is the problem of the clear inspection left. As mentioned, for reasons of safety the diameter of the esophagoscope had to be much reduced. Consequently the picture seen at the end of the long tube is a small one. Its interpretation therefore can be difficult. Some mucus or blood may make the examination still more difficult. If there is a pathologic prominence, biopsy is usually required to determine its nature. This condition seems unsatisfactory to the internist who is used to the brilliant pictures of cystoscopy and gastroscopy.

A NEW ESOPHAGOSCOPE

The idea of constructing an esophagoscope having an optical system was conceived. It is not a new idea, however. It was, among others, tried by Glücksmann[6] and by Henning. Two solutions had to be considered, namely, to construct either an outer optical attachment or an optical system to be introduced into the esophagoscopic tube itself. The latter, more difficult way was chosen because of the more brilliant pictures and the better magnification available. The chief problem was to keep the esophageal mucosa away from the optical objective. This was solved by the construction of two metal shells covering the objective at introduction and being spread after introduction. Thereby the mucosa is removed to the proper distance. The objective itself had to be constructed different from that of a cystoscope or gastroscope. In the esophagus, side views could be of no avail. One has to look forward into a tube, and the prism used in cystoscopy and gastroscopy had to be abandoned in favor of a forward-looking objective lens. It seemed questionable whether it would be possible to keep such a lens clean, since one might think that it would be easily smeared by esophageal secretion. Preliminary attempts with a makeshift instrument in 1943 at Cook County Hospital, Chicago, proved that with the proper position of the patient

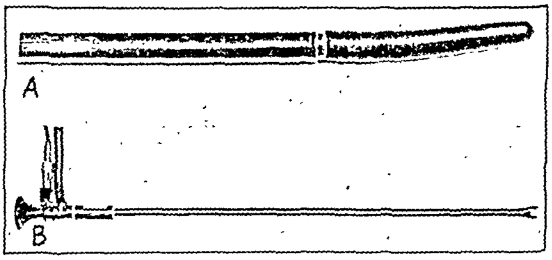

Fig. 2.—*A*, tip of instrument with obturator. *B*, instrument after removal of obturator and insertion of optical apparatus. Shells are spread to remove mucosa from objective.

and with the proper technic clear pictures could be obtained. Therefore such an instrument—a safe diagnostic optical esophagoscope—was constructed (American Cystoscope Makers, Inc., New York). It yields sharp pictures with high magnification, with which every detail can be readily recognized. This instrument is so thin (10 mm.) that the discomfort for the patient is minimal, if proper anesthesia is used (fig. 2).

Although the pictures seen are distinct and clear, it seemed desirable to add a biopsy forceps for the diagnosis in those cases in which an obstruction exists, but inspection does not permit the decision whether it is benign or malignant. This biopsy forceps is constructed also in junction with a magnifying optical system.

Similar optical attachments for air injection needle (treatment of varices) and a grasping forceps (extraction of foreign bodies) may be feasible and may change the diagnostic instrument into a therapeutic one.

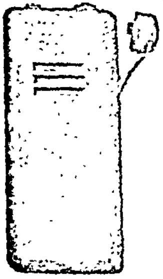
Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

OTARION HEARING AID MODEL E-2 ACCEPTABLE

Manufacturer: Otarion Hearing Aids, 159 North Dearborn Street, Chicago 1.

This instrument is a three tube air conduction hearing aid, with the batteries contained in the amplifier case. The case is constructed of die-cast magnesium alloy, coated with vinyl resin finish, ivory in color. A side-hinged full length back cover gives access to the battery compartments and the three tubes, which are readily accessible. The magnetic type receiver is connected to the amplifier case by means of a light plastic-covered cord which has dual pin plugs at each end.



Otarion Hearing Aid, Model E-2

Two wheel-type controls are placed at the top of the case. One is a volume control; the other is a combination "on-off" switch and tone control with three settings: 1 dot, full tone range; 2 dots, slight low frequency attenuation; 3 dots, greater low frequency attenuation. A detachable wearing or attachment clip fastens either to the front or the back of the case.

The Otarion Model E-2 contains a built-in voltmeter, called a Metrodyne, by means of which the voltages of either the A or the B battery can be checked whenever desired.

The dimensions are 133 by 64 by 33 mm. (5¼ by 2½ by ⅞ inches) and the weight is 170 Gm. (6 ounces). The A battery of the zinc and carbon type is 1.5 volts and the B battery of the zinc and carbon type is 30 volts. The A battery drain is 50 milliamperes and the B battery is 0.8 milliampere.

Acoustical Gain for Pure Tones (maximum gain in decibels for each of 6 frequencies and 3 settings of the tone control):

Position of Tone Control	Frequency					
	250	500	1,000	2,000	3,000	4,000 cycles
1 dot	51	55	62	63	65	50 db.
2 dots	46	53	61	63	65	50 db.
3 dots	40	48	58	63	65	50 db.

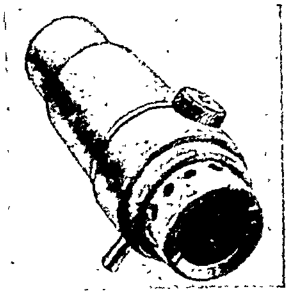
Acoustical Gain for Speech.—The maximum gain, when the tone control was set at the 1-dot position, was 55 decibels. This value was obtained on two different hard of hearing persons, each of whom is an experienced user of hearing aids and has approximately 60 decibels unaided loss for speech with a speech audiometer. These persons perceived speech with 55 decibels less intensity through a high quality sound amplification system (speech audiometer) in a sound-proof room with the hearing aid than without it. Note: This high gain for speech was obtained on experienced users of hearing aids with predominantly middle ear types of hearing impairments, which type of impairment obtains best results with hearing aids. This amount of gain with a hearing aid cannot be anticipated by persons with inner ear impairments.

The Council on Physical Medicine voted to include the Otarion Hearing Aid Model E-2 in its list of accepted devices.

POCKET SIZE ELECTRONIC STETHOSCOPE ACCEPTABLE

Manufacturer: American Medical Instrument & Supply Corp., 5 North Wabash Avenue, Chicago 2.

The Pocket Size Electronic Stethoscope is an instrument designed to amplify the sounds picked up during auscultation. It is roughly cylindric in shape and weighs about 225 Gm. (8 oz. avoirdupois). The length is 14 cm. (5½ inches), the diameter 5 cm. (2 inches) and the shipping weight 450 Gm. (1 pound). This does not include the necessary binaural fittings and rubber tubing. The needed electrical power must be supplied by a mercury type A battery and a 22½ volt zinc-carbon B battery.



Pocket size Electronic Stethoscope

The Council obtained evidence that the instrument had given satisfactory service in the hands of practicing physicians with normal hearing and that it gave increased accuracy of diagnosis in some cases. It was particularly helpful to physicians with impaired hearing.

The Council on Physical Medicine voted to include the Pocket Size Electronic Stethoscope in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT TO THE COUNCIL

The Council has authorized publication of the following progress report from the Therapeutic Trials Committee.
Austin Smith, M.D., *Secretary.*

ACTIVITIES OF THE THERAPEUTIC TRIALS COMMITTEE

The Therapeutic Trials Committee was organized as a standing committee of the Council on Pharmacy and Chemistry and commenced its operations in April, 1946. Although considerable attention has been devoted to matters of organization and procedure during the intervening two and one-half years, a number of significant problems have been commenced under Committee auspices, and it is deemed appropriate to summarize briefly the accomplishments of the Committee and the investigators working under its aegis.

The work of the Committee can conveniently be divided into three sections: (1) investigations pursued under Committee contracts, (2) collaborative projects, and (3) educational and informational services. It must be emphasized that no problem undertaken by the Committee has as yet been completed and, therefore, detailed reports on Committee investigations cannot be presented. Comments on the general trend of these investigations are offered, but it should be understood that no conclusions are permissible until the research has been completed.

Investigations Pursued Under Committee Contracts

Because of the terms of the contracts, it is not possible to identify the investigators or the sponsoring firms involved in the investigations mentioned below. On completion of these investigations it is anticipated that full reports will be published by the authors for the benefit of the medical profession.

Streptomycin Therapy of Granuloma Inguinale.—Although several reports of the efficacy of streptomycin in the treatment of granuloma inguinale have appeared, it was felt desirable to encourage additional studies in order to determine, on a large number of patients, the precise usefulness of this agent. The results so far reported to the Committee confirm the efficacy of streptomycin, but since the effective dose appears to be large, investigations are proceeding to determine whether combined streptomycin-antimony therapy may be more efficacious and less likely to induce undesirable side-actions.

Aludrine Sulfate (Isopropyl Epinephrine) Therapy of Bronchial Asthma.—Aludrine-Sulfate, a preparation first tried clinically in Germany during the last war, has been found to have a profound bronchodilator action in laboratory animals and, unlike epinephrine and ephedrine, to have a vasodilator action. It was thought desirable to investigate more thoroughly its effects in bronchial asthma.

Preliminary work indicates that it is not as potent in clinical asthma as is indicated by animal studies. Furthermore, when given by intramuscular injection or by mouth in doses sufficient to exert a significant bronchodilator effect, patients may experience typical anginal attacks and show electrocardiographic changes compatible with coronary constriction. There is some indication that these serious side-effects can be mitigated by administering the drug sublingually and by inhalation. A report has been submitted by the responsible investigators and will be published shortly.

Chlorophyll Therapy of Wounds and Ulcers.—Numerous reports have been published regarding the efficacy of solutions and ointments containing chlorophyll in decreasing the healing time of wounds and ulcers, particularly those which showed delayed healing or were indolent. In an attempt to secure a more critical evaluation of chlorophyll therapy, two investigations are being conducted under Committee auspices. The first, dealing with the actions of a solution and an ointment of chlorophyll on the rate of healing of wounds involves the use of a method originally devised by Smelo[1] and quantitative measurements of the rate are being made by a technic based on observations of Carrel and Hartman[2] and adapted by DuNouy.[3] In the small series of patients studied to date, 25 per cent have shown acceleration of wound healing. Where significant variables were eliminated, 37 per cent of the patients showed accelerated healing.

A second investigation involving the study of a chlorophyll solution in the treatment of certain chronic nasopharyngeal conditions is underway but no reports of progress have as yet been submitted to the Committee.

Methyl Cellulose as a Laxative.—Work is just commencing on a clinical study designed primarily to study various factors involved in chronic forms of constipation and to evaluate the possible usefulness of methyl cellulose as compared to other bulk-producing laxatives and lubricants.

Adjusted Ophthalmic Solutions.—Because of the unsatisfactory state of our knowledge concerning the optimum physical-chemical properties for solutions of drugs intended for ophthalmic use, a request was made to the Committee for an investigation of such factors as p_H, isotonicity, stability of the drug, etc., on the effect of these solutions on the human eye. Arrangements have been made for this investigation, and the work will get under way in the near future. The results of this study should be of importance not only to ophthalmologists but also to pharmacists and pharmaceutical manufacturers.

Collaborative Investigators

Two problems have been presented to the Committee which, because of their magnitude, have required the appointment of special subcommittees to plan and evaluate the investigations. Furthermore, the active collaboration of competent investigators has been necessary in order that all phases of these problems receive adequate exploration.

Estrogens and Androgens in Mammary Cancer.—A report outlining the background of this study has been published.[4] Forty-eight clinics are participating in this study. Each investigator is pursuing a problem of his own choosing, often in a larger field of research. In order to make his data available for pooling with those of others, he conforms to certain minimal requirements established by the Subcommittee on Steroids and Cancer, which permit him to choose one of several dosage schedules but require comparisons to be made with certain standard schedules. Certain minimal laboratory examinations are required on each patient, but the investigator is encouraged to use his own ingenuity and widen the problem in the direction wherein lie his own particular interests.

Four dosage schedules of testosterone propionate are being investigated in order to determine the minimum dose to produce definite effects on the primary tumor or its metastases. These are: 75 mg. weekly, 150 mg. weekly, 300 mg. weekly, and 600 mg. weekly. Testosterone therapy is being directed primarily against bony metastases although observation of the effects of this hormone on soft tissue lesions, especially in younger women, is being made.

Six different estrogens are also under study for their effects on soft tissue and bony lesions, particularly in older women. The estrogens and dosage being used are as follows: diethylstilbestrol, 15 mg. daily; dienestrol, 15 mg. daily; dimethyl ether of diethylstilbestrol, 30 mg. daily; ethinyl estradiol, 3 mg. daily; "premarin," 30 mg. daily; and estradiol dipropionate, 5 mg. three times in the first week and 5 mg. twice weekly thereafter.

A uniform system of reporting cases has been established and all case reports and progress reports will be reviewed and evaluated by the Subcommittee on Steroids and Cancer, composed of Dr. Ira T. Nathanson, Boston, Chairman, Dr. Frank Adair, New York, Dr. Willard Allen, St. Louis, and Dr. Earl Engle, New York. Through the courtesy of Col. J. E. Ash, the facilities of the American Registry of Pathology have been made available to the Committee and all pathologic material obtained at biopsy, operation, or autopsy of patients admitted to this study will be deposited at the Army Institute of Pathology as a permanent collection. This material will be reviewed and evaluated by three consultants in pathology: Dr. Howard T. Karsner, Cleveland, Dr. Fred Stewart, New York, and Dr. Shields Warren, Boston.

Similarly, duplicates of significant roentgenologic films will be prepared and deposited at the Registry of Roentgenologic Pathology, where they will be reviewed by three consultants in radiology: Dr. L. H. Garland, San Francisco, Dr. Leo Rigler, Minneapolis, and Dr. Merrill Sosman, Boston.

The active cooperation of the American Cancer Society through the Committee on Growth of the National Research Council and of The National Advisory Cancer Council of the United States Public Health Service has been secured. These agencies have reviewed applications for grants in aid from participating investigators and have in most instances granted the sums requested for carrying on this work. None of the funds so granted have been given to the Committee nor has the Committee sought financial assistance from outside sources to defray the expenses incident to the coordination of this project.

Fourteen pharmaceutical firms have agreed to supply large quantities of testosterone and estrogens to the Committee for use in this study. These firms have been most generous with these costly materials and their wholehearted cooperation is appreciated by the Committee. The cooperating firms are:

Abbott Laboratories.
Ayerst, McKenna & Harrison, Limited.
Ciba Pharmaceutical Products, Inc.
Charles E. Frosst & Co. (Canada),
Lakeside Laboratories, Inc.
Rare Chemicals, Inc.
Roche-Organon, Inc.
Schering Corporation
Schering Corporation Limited (Canada)
E. R. Squibb & Sons.
The Upjohn Company.
Wallace & Tiernan Products, Inc.
White Laboratories, Inc.
Winthrop-Stearns, Inc.

Although the actual investigations did not commence until March, 1948, more than 235 cases of breast cancer were under study by 26 investigators by the middle of October, as shown by case reports filed with the Committee. It is much too early to draw any conclusions regarding the palliative effects of these hormones in breast cancer. It can be said, however, that perhaps 20 to 25 per cent of the patients show some definite beneficial subjective or objective improvement. To be answered are such questions as the duration of palliation, particularly in comparison to the results known to occur following adequate roentgen irradiation; the physiologic or pathologic factors governing favorable responses; the mechanism by which regres-

sive changes in the tumors are brought about, and the most satisfactory preparations and doses to be used.

From time to time reports on this project will be published by the Committee and by the individual collaborators. The material from which these reports are prepared will be available to physicians and other scientists at the American Registry of Pathology in Washington, D. C.

Evaluation of Moist Heat in Poliomyelitis..—At the request of the National Foundation for Infantile Paralysis, the Committee agreed to investigate the feasibility of designing and conducting a coordinated clinical investigation to determine the precise value, immediate and remote, of moist heat in the treatment of acute poliomyelitis. A Subcommittee composed of Dr. William T. Green, Boston, Dr. Derek Denny-Brown, Boston, Dr. Hugo Muench, Boston, and Dr. James L. Wilson, Ann Arbor, was appointed. The Subcommittee drafted a preliminary report indicating that such a study would be feasible and outlined in general terms the experimental design for such a project. This report was submitted to The National Foundation, which subsequently requested the Committee to draft detailed plans and a budget for such an investigation for consideration by their Medical Advisory Committees.

The difficulties inherent in studying the effects of any therapeutic procedure in poliomyelitis are caused by the variability and unpredictability of the disease and by the emotional aura which surrounds the scientist seeking objective data in any condition which affects children or which produces crippling. These difficulties can be overcome only by the establishment of rigid controls in the clinical investigation and securing the cooperation of competent and critical investigators who will sacrifice their freedom of individual action in order to follow predetermined protocols established by the Committee.

Fortunately, several such investigators have been found who have indicated a willingness to participate in such a project if The National Foundation for Infantile Paralysis decides to proceed with the investigation outlined by the Committee.

Although all details of the investigative program have not been worked out, it is apparent that it will cost a great deal of money to do a properly critical investigation. One of the questions which The National Foundation will have to decide is whether the expected results of such a program will justify the expenditure of large sums of money.

Educational and Informational Projects

Besides the sponsorship of clinical investigations, the Committee is undertaking to collect information and publish reports of a general nature which may be of interest to the medical profession and to research workers. One such article, "The Cost of Clinical Research" has already been published.[5]

A group of Consultants in Statistical Methods has been formed, comprising Dr. J. Harold Austin, Philadelphia, Dr. Errett C. Albritton, Washington, Dr. George F. Badger, Cleveland, Dr. Ross L. Gauld, Washington, Dr. H. M. C. Luykx, New York, and Dr. Everett L. Welker, Chicago, who are considering the preparation of a series of articles on the design of experiments and the evaluation of data for the benefit of the medical profession.

More than forty institutions engaged in medical research have been visited by the Secretary of the Committee and the facilities and research interests of the investigators of these forty institutions have been tabulated and indexed.

Liaison has been maintained with the Food and Drug Administration, Research Grants Division of The National Institute of Health, and The National Research Council. An effective interchange of information of mutual interest has been established.

From time to time additional activities will be developed to make the Committee more useful to the medical scientist and to the profession in general. It is believed, however, that the activities of the Committee since its establishment two and a half years ago demonstrate the wisdom of the Council on Pharmacy and Chemistry in thus extending the scope of its interests.

Chester S. Keefer, M.D., Chairman.
Walton Van Winkle Jr., M.D., Secretary.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

ROCKY MOUNTAIN SPOTTED FEVER VACCINE.—Vaccine prepared from membranes of embryonated chicken eggs infected with Rickettsia rickettsii. Rocky Mountain Spotted Fever Vaccine is prepared from a saline suspension of infected chick embryo membranes. The suspension, after inactivation with formaldehyde solution, is extracted with ether, according to a modification of the method of Craigie (*Canad. J. Res. E.*, **23**:104, 1945), to remove yolk lipids and tissue debris, yielding an almost water-clear solution which contains the immunizing antigen.

Actions and Uses.—There is considerable amount of evidence that a vaccine preparation is of value in the prevention of Rocky Mountain spotted fever (tick typhus), a rickettsial disease due to Rickettsia rickettsii which is widely ditsributed in the United States, being especially prevalent in Maryland, Virginia and North Carolina as well as in some parts of the Rocky Mountain regions. In the western United States the common vector is D. andersoni which is rarely found in urban centers; while in the eastern United States both urban and rural areas may be infested with the common vector, the dog tick, D. variabilis. The vaccine originally was made from artificially cultivated and infected ticks. More recently, this has been replaced by the infected membranes of the embryonated chicken eggs.

The vaccine leads to the development of active immunity, the duration of which is not known. The question as to whether the vaccine should be employed depends to a large extent upon the likelihood of exposure to infection. When exposure is likely it is advisable to repeat the vaccination annually. In areas in which the risk is large, the vaccine would be recommended especially for ranchers, campers and others, while in areas in which the disease is rare, vaccination hardly can be justified. The vaccine contains egg protein, hence should not be given to persons sensitive to egg protein.

Dosage.—0.5 cc. to 2.0 cc., depending on the age of the subject, to be repeated once or twice at intervals of from 5 to 10 days.

E. R. Squibb & Sons, New York

Rocky Mountain Spotted Fever Vaccine: 4 cc. vials. Preserved with sodium ethylmercurithiosalicylate 1:10,000.

PENICILLIN (See New and Nonofficial Remedies 1947, p. 144).

The following dosage forms have been accepted:

Eli Lilly & Company, Indianapolis

Crystalline Penicillin G Potassium: 100,000, 200,000, 500,000 and 1,000,000 units, 20 cc. vials.

Ointment Crystalline Penicillin G Potassium: 1,000 units per gram, 28 Gm. tubes.

Ophthalmic Ointment Crystalline Penicillin G Potassium: 1,000 units per gram, 3.5 Gm. tubes.

Troches Crystalline Penicillin G Potassium: 5,000 units.

Commercial Solvents Corp., New York

Crystalline Procaine Penicillin G in Oil: 300,000 units per cc., in peanut oil, 10 cc. vials.

MERTHIOLATE (See New and Nonofficial Remedies 1947, p. 96).

The following dosage form has been accepted:

Eli Lilly & Company, Indianapolis

Ointment Merthiolate: 1:1,000, 28 Gm., 450 Gm. (1 lb.) and 2.26 Kg. (5 lbs.) jars. Merthiolate 0.1 per cent in a hydrophilic ointment base.

AMINOPHYLLINE-U. S. P. (See New and Nonofficial Remedies 1947, p. 305).

The following dosage form has been accepted:

Estro Chemical Co., Inc., New York

Solution Aminophylline: 0.25 Gm., 10 cc. ampuls; 0.5 Gm., 2 cc. and 20 cc. ampuls.

LYMPHOCYTES AND GLOBULIN

At a recent conference on lymph held by the New York Academy of Sciences, White and Dougherty[1] presented important statements on the newer knowledge of lymphocytes. The Yale investigators said that the structure and function of lymphoid tissue are controlled by pituitary-adrenal cortical secretion and that changes can be observed in this tissue following stimulation of the pituitary or the administration of adrenal cortical preparations. The changes are: a dissolution of lymphocytes in lymphoid structures, a profound lymphopenia, an increase in serum beta globulins and gamma globulin and, in the immunized animal, a release of antibody globulin to the circulation.

The dissolution of lymphocytes is characterized by a shedding or budding of the lymphocyte cytoplasm. As a consequence, this material is released to the lymph and, thus, to the systemic circulation. Lymphocytes, in the normal animal, contain a protein identical with the normal serum gamma globulin; a second component of lymphocytes is probably identical with the beta globulin of serum. Therefore, the accentuated cytoplasmic budding of lymphocytes, resulting from augmented adrenal cortical hormone concentration, causes an increased amount of lymphocyte globulins in the blood.

The increased dissolution rate of lymphocytes within lymphoid structures results in a failure of delivery of these cells to the circulation. The adrenal cortical steroids controlling lymphocyte dissolution are those which are oxygenated in position 11 of the steroid nucleus. Thus the peripheral lymphopenia following acute adrenal cortical stimulation is a readily determined manifestation of adrenal cortical activity. The presence of acute lymphopenia may be accepted as evidence that the sequence of events described is taking place.

Lymphocytes are the most widely distributed cells in the body. The release of the protein of lymphocytes following augmented pituitary–adrenal cortical secretion suggests that lymphocytes are a storehouse of readily available protein. This protein may be a significant portion of the reserve or deposit protein and the source of a large proportion of the extrahepatic nitrogen which appears in the urine in conditions of stress. Involution of lymphoid tissue and the loss of nitrogen from lymphoid tissue as a result of fasting occur only in the presence of intact adrenals. In the adrenalectomized animal, the reserve protein present in lymphocytes cannot be released during a period of fast. The availability of this protein in other circumstances of stress also probably depends on the presence of the pituitary and the adrenals.

An intimate relationship has been demonstrated between plasma globulins and lymphocyte proteins. The cytoplasmic proteins of lymphocytes and the hormonal control of their release attain added significance in the light of the various stimuli, including hemorrhage, chronic inanition, injection of heterologous protein or protein derivatives and irritation of the peritoneum, which activate the pituitary–adrenal cortical mechanism.

The demonstration of the high nutritive value of gamma globulin, a normal constituent of lymphocytes, adds importance to the role of these cells in protein metabolism. Indeed, the lymphocyte may bear a relationship to protein metabolism similar to that of the fat cell to lipid metabolism.

A portion of the protein of lymphocytes in the immunized animal is labeled globulin or antibody, and the rate of release of this protein is regulated by the same factors that control release of protein from lymphocytes in the nonimmunized animal. The demonstration of the basis of the anamnestic response is proof that lymphocytes are a storehouse of protein. Animals without circulating antibody have been shown to have antibody within their lymphocytes, and this labeled globulin is released to the circulation, as a result of increased supply of pituitary–adrenal cortical hormones. Increased secretion of the animal's own adrenotropic hormone may occur in response to a wide variety of stimuli which are known to activate pituitary–adrenal cortical secretion. Hemorrhage, cold, heat, bacterial toxins, foreign proteins and toxic chemical agents all activate the hormonal mechanism and have been used to demonstrate the anamnestic response. Several investigators have suggested that reticuloendothelial cells are concerned with the production of immune globulin.

As lymphocytes have been demonstrated to contain antibody, it is evident that, as these cells reproduce themselves, the labeled globulin constituent of the cytoplasm is transferred to the daughter cells. Tumors which developed from transplants of antibody-containing malignant lymphocytes were shown to contain as much immune globulin as the tumor from which the tissue was taken for transplantation. Therefore, factors which increase the number of lymphocytes will also augment production of antibody by increasing the available potential store of immune globulin.

---

[1] White, A., and Dougherty, T. F.: Role of Lymphocytes in Normal and Immune Globulin Production, and the Mode of Release of Globulin from Lymphocytes, Ann. New York Acad. Sc. **46:** 859 (Sept.) 1946.

The presence of antibody in lymphocytes gives added significance to the wide distribution of these cells in the body. At least one major function of the lymphocytes which are infiltrating into all of the tissues of the body is, no doubt, to serve as a medium of distribution of gamma globulin. The recent demonstration of the high nutritive value of gamma globulin suggests that lymphocytes supply to cells throughout the body a protein which may fulfil nutritive and, perhaps, other physiologic needs of the body cells.

Some investigators have not been able to confirm the theory mentioned, particularly the part which relates to the dissolution of lymphocytes with the release of globulin antibodies. The differences in results attained by the various critics of this theory perhaps will stimulate further research on lymphocytes as well as antibodies, about which important subjects far too little is known.

DIABETES DUE TO ALLOXAN

Diabetes mellitus was first produced experimentally in dogs by von Mering and Minkowski in 1889 by means of total extirpation of the pancreas. G. F. Young in 1937 produced diabetes in dogs by daily injection of extracts of anterior pituitary for a period of several weeks. Dunn, Sheehan and McLetchie,[1] while attempting to elucidate the pathogenesis of the crush syndrome, administered alloxan to various animals in an effort to establish tubular nephritis. Many animals died during the first day. Investigation of these deaths revealed acute necrosis of the islet tissue of the pancreas. The development of this lesion was accompanied by an initial rise of the blood sugar, followed by intense hypoglycemia; they believed that the lesion was caused by overstimulation of the islets with overproduction of the insulin and later death of the cells by overstrain. Jacobs[2] first described the initial hyperglycemic and hypoglycemic phases following intravenous administration of alloxan in rabbits, and observed the symptomatic relief of the hypoglycemia by the administration of glucose. Later the phase of hyperglycemia was added to the picture.

The production of diabetes without nephritis is dependent on the difference between the nephrotoxic and diabetogenic doses. Early death following injection of alloxan could be prevented by prophylactic administration of glucose. When animals were thus sustained during the period of hypoglycemia, they survived and became permanently diabetic. Dunn and McLetchie, Baily and Baily, Goldner and Gomori and Houssay and his co-workers produced sustained diabetes due to alloxan in rats, rabbits, dogs, monkeys and cats. Diabetes due to alloxan, according to Lukens,[3] is a partial pancreatectomy produced by a chemical agent the effect of which is to cause selective degeneration of the beta cells. The subsequent diabetes may vary from the mildest to the most severe type. Diabetic animals respond readily to insulin. The diabetes may be controlled by the regular use of insulin. Large doses of alloxan produce severe diabetes and renal insufficiency terminating in acidosis and coma.

The most striking complication of diabetes due to alloxan in rats and rabbits has been the development of cataract. The incidence of cataract is greater and the appearance time shorter when diabetes is severe. In addition to cataract one group of investigators has reported the occurrence of retinal lesions consisting of capillary hemorrhages. Chestler and Tislowitz observed that immature rats with diabetes due to alloxan were strikingly dwarfed, some remained sexually infantile, and the intestinal tract was enlarged in proportion to body weight.

Pathologic studies of diabetes due to alloxan emphasize that injury from alloxan takes place within a few minutes of its injection and that the subsequent alterations are the consequence of this initial injury. The changes which begin immediately after the injection of alloxan progress to the complete disintegration of the beta cells within six hours, that is, at the onset of the hypoglycemic phase. The final picture after diabetes has existed for a few weeks is that of striking atrophy of the islands. The acinar tissue is usually normal. The toxicity of alloxan for the beta cells of the islands of Langerhans is accompanied by damage of the renal tubules. The thyroid, parathyroid and pituitary glands are usually described as normal. The liver has been reported by most observers as normal. Adrenal glands increase in weight in alloxan as in pancreatic diabetes.

Alloxan was first given to man by Brunschwig[4] and his co-workers to relieve hyperinsulinism due to islet cell carcinoma. They also gave it to 4 patients with severe malignant disease of other types. The 4 persons with normal blood sugar had a negligible hyperglycemic phase and no evidence of diabetes. Increasing amounts were given over periods up to six days. This experience suggested that man is resistant to alloxan. Conn[5] reported a case of a man with a pancreatic islet cell tumor and hyperinsulinism. The patient was given a nine day course of alloxan injections. At operation the tumor was found and removed. The islets of the pancreas proper were found to be severely damaged. Immediately on removal of the tumor typical diabetes mellitus developed. This experience suggests that the pancreatic islet tissue of human beings is sensitive to alloxan. Conn's experience contradicts the repeatedly expressed opinion that human islet tissue is exceedingly resistant to the degenerative effects of alloxan.

[5] Conn, J. W., in discussion on Bailey, C. C.; Bailey, O. T., and Leech, R.: Alloxan Diabetes, Proc. Am. Diabetes A. (1946) **6**: 375-393, 1947.

Present evidence indicates that the action of alloxan on the islands of Langerhans is exerted directly. The pathologic changes are believed to be the consequences of an immediate toxic injury of the beta cells. The initial hyperglycemic phase has been prevented by insulin, phlorizin, adrenalectomy, hypophysectomy and hepatectomy. The most generally accepted hypothesis, according to Lukens, is that preformed insulin is liberated from the damaged islets. Diabetes due to alloxan is a valuable aid in the study of diabetes. Evidence does not indicate that alloxan is related to human diabetes mellitus.

UNDERSTANDING PEOPLE

Science during the next century, said Roger J. Williams, addressing the Centennial Meeting of the American Association for the Advancement of Science, will predominantly be occupied with human science. Physical sciences and their applications will continue to thrive, but the most significant development of the next century, he believes, will be in the realm of human science or of understanding people. Social problems can be solved only if we understand what people are like. Human beings, Williams believes, should be studied anatomically, physiologically, psychologically and in their social relations. Differentiation or individuality is a potent factor in every social problem. One of the crucial tests in understanding people is to know how they are alike and how they differ from one another. Probably inequalities are the very basis of our democracy. If we were all the same and had the same likes and dislikes, there would be no need for freedom. We would all fall readily into the same pattern of life, and difficulties would never arise. Because we do have individuality we want freedom to make our own decisions and live our own lives.

People differ one from another because of their inheritance and because of the differences in environmental influences. The relative importance of the two factors is a matter of conjecture and opinion. Inherent individuality is most highly developed in man. Superimposed on these inherent differences are differences induced by environmental and cultural influences.

People differ in the size and shape of their bodies and their heads, noses, hands, feet and legs. Individuality in shape, size and cellular composition are just as pronounced with respect to our thyroids, our adrenals, our sex glands and our pituitary glands. It is, therefore, not surprising that we do not always see eye to eye and that our other senses do not work uniformly for all of us. Williams cites an experiment in which a chemical was tested in a special study of 6,377 persons. Of those who tested it 21.3 per cent found it tasteless, 64.5 per cent found it bitter, many extremely so, 5.4 per cent found it sour, 2.1 per cent found it sweet, 4.8 per cent found it salty and the remaining 1.9 per cent ascribed to it miscellaneous other tastes.

The work of Beadle and his associates demonstrated that people inherit through the agency of genes their entire metabolic machinery, and, since each inheritance is distinctive, it follows that everyone has metabolic machinery that is distinctive. The most apparent outward manifestation of the existence of distinctive metabolic patterns is the existence of allergies and differences in the responses to drugs.

Williams also stresses that intelligence is not a unitary trait possessed in high degree by some and in low degree by others. There are many different ways in which one can be intelligent. The most compelling evidence of this fact is the existence of the so-called idiot-savants. Williams feels that the greatest benefits to be derived from a revised school system will come from recognition and care for individuality. The schools of the future will devote considerable effort in the earliest grades to helping the students to become acquainted with themselves.

Current Comment

ATOMIC ENERGY COMMISSION FELLOWSHIPS

The Atomic Energy Commission has established a fellowship program for physicians who desire to be trained and carry on research in the field of atomic energy as it relates to medicine. The Commission requested the National Research Council to undertake the administrative responsibilities of the fellowship program. A committee has been established in the Council which considers applications from physicians under 35 years of age who have had one year internship or equivalent training. The fellowships, which are for one year, may be renewed. The candidate is expected to enroll in nuclear radiation physics, pertinent mathematics and certain courses in chemistry. He may make arrangements for this instruction and, if that is not feasible, may attend one of the regional training centers which have been established by the Atomic Energy Commission. This basic training will comprise lectures, laboratory exercises and demonstrations for about six months, after which fellows will have an opportunity to participate in research projects which the Atomic Energy Commission is supporting at various institutions throughout the United States. Fellows will be able to maintain contact with clinical medicine through the affiliated medical schools and hospitals. The Commission has released the names of forty-four fellowships recently awarded under this program. Five classes of research fellowships have been established, including not only medical science but physical, biologic and agricultural sciences as well. The postdoctoral fellowships carry a basic stipend of $3,000 a year, the predoctoral a basic stipend of $1,600 a year, and these may be increased to provide for support of dependents or other special needs of the fellows. The Atomic Energy Commission considers this program an integral part of its activities. There is a shortage of scientific personnel in medical and allied fields as they relate to atomic energy.

ORGANIZATION SECTION

Official Notes

SCIENTIFIC EXHIBIT—ATLANTIC CITY SESSION

The Scientific Exhibit will mark its Fiftieth Anniversary at the Atlantic City Session, June 6-10, 1949. This feature of the meeting was started in 1899 as a pathology exhibit, and in 1903 was expanded to include all branches of medicine. Awards for the best exhibits have been made since 1908.

At the coming meeting in Atlantic City, each of the eighteen Sections of the Scientific Assembly will sponsor a group of exhibits. Final selection of exhibits and assignment of space will be made after all applications have been received by the Committee on Scientific Exhibit of the Board of Trustees, consisting of Dr. Dwight H. Murray, Napa, Calif.; Dr. E. J. McCormick, Toledo, Ohio, and Dr Gunnar Gundersen, LaCrosse, Wis.

Application blanks for space in the Scientific Exhibit at Atlantic City are now available and may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10, Ill.

COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE

The American Medical Association's Council on National Emergency Medical Service held its third regular meeting in Chicago, November 1. This agency of the Board of Trustees, established in 1947, is dedicated to a continuous study of the medical, health and sanitary needs of the nation's armed forces, industry, agriculture and the civilian population at large in time of national stress, disaster and emergency.

In attendance were Dr. Roscoe L. Sensenich, President of the Association; Dr. Elmer L. Henderson, Chairman of the Board of Trustees; Dr. Morris Fishbein, Editor of The Journal of the American Medical Association; Dr. James E. Paullin and Dr. Edward L. Bortz, both former Presidents of the Association, and Dr. James C. Sargent, Chairman of the Council. In addition to the Council members and consultants, approximately twenty-five other physicians, including Council secretaries and Bureau directors of the Association, were present. Dr. Carl Peterson, Secretary of the Council on Industrial Health, reported that in the event of another war the success of an industrial health program now universally recognized as a vital factor in defense would largely depend on the complete coordination of military and civil work. Appropriate steps, he disclosed, have already been undertaken to assure a comprehensive plan to meet the emergency. Dr. James R. Wilson, Secretary of the Council on Foods and Nutrition, reported briefly on the subject of nutritional aspects of national security. Dr. Donald G. Anderson, Secretary of the Council on Medical Education and Hospitals, analyzed the medical graduate training program now in operation by the Armed Forces. Mr. Edwin Holman, representing Mr. J. W. Holloway Jr., Director of the Association's Bureau of Legal Medicine and Legislation, reported on legal aspects of legislation in connection with the Selective Service Act.

The Council, mindful of its responsibilities to the profession and the public at large and giving heed to the threat of atomic warfare, took cognizance of the fact that certain of its basic recommendations require reiteration by the Association. With the view in mind of placing increased emphasis on the medical phase of planning for national defense, it was recommended that the Board of Trustees reintroduce the following resolutions to the House of Delegates:

Be it Resolved, "That the President of the United States of America and the Congress be respectfully urged:

"That in peace as in time of war the Surgeon General of the Army, the Surgeon General of the Department of the Navy and the Air Surgeon, Department of the Air Force, have the authority and responsibility for participation, with commensurate rank and at the level of the Chiefs of Staff and the Chiefs of Naval Operations of the Armed Forces, in all military and naval planning, organization and operations as these relate to medical, health, sanitary and welfare services and for the assignment and utilization of medical and allied personnel at home and abroad."

Be it Resolved, "That the American Medical Association, by action of its House of Delegates, desires to assure the highest type of professional care for the members of the Armed Forces. It is imperative that a permanent 'Civilian Medical Advisory Board' be established by the Secretary of Defense with the least possible delay. This 'Civilian Medical Advisory Board' to be composed of doctors of medicine, appointed from civilian life by the Secretary of Defense and responsible under policies established by him for the development of all medical policies, procedures and programs required by the medical and hospital services of the Armed Forces and to affect the utmost coordinated efforts between the several departments, boards and agencies of the Armed Forces."

In addition, the Council, with the view in mind of being helpful to the Armed Forces in the solution of their present medical personnel problem, recommends that the Board of Trustees introduce the following proposed resolution to the House of Delegates:

Be it Resolved, "That in the light of current medical personnel shortages, and in line with the accepted policy for coordination by the Armed Forces, every effort should be made to consolidate the facilities for the hospital care of the several Armed Forces.

"That the patient load in military hospitals, particularly of non-military patients, be reduced to the minimum consistent with the primary mission of the Armed Forces as defined by Congressional Acts."

Washington Letter

(From a Special Correspondent)

Nov. 11, 1948.

All 7 Physician Representatives Returned to Congress

The radical change in the complexion of the House of Representatives which was produced by the national elections did not remove any of the seven incumbents who are doctors of medicine. All were reelected. They are: (Republicans) Drs. Ivor D. Fenton, Pennsylvania; Walter Judd, Minnesota; A. L. Miller, Nebraska, and Frederick C. Smith, Ohio; (Democrats) E. H. Hedrick, West Virginia; Thomas E. Morgan, Pennsylvania, and Joseph L. Pfeifer, New York.

Oddly enough, none of the physician members of Congress is a member of the House Interstate and Foreign Commerce Committee, which handles virtually all proposed legislation pertaining to medical research and health economics. It is this committee which, in the 81st Congress, will hold hearings on national health insurance, expansion of the U. S. Public Health Service, extension of child health activities by the federal government, amendment of the Hill-Burton hospital construction law, food and drug legislation and modification of federal cancer and venereal disease control statutes.

However, with the Interstate and Foreign Commerce Committee due to be reorganized and many new faces added as a result of the election, it is not improbable that at least one physician will join its membership. Five of its Republican members were defeated. Three of its Democrats are gone, one by retirement, one by defeat at the polls and one by promotion to the Senate (Chapman, Kentucky). This means that eight Democrats and, in event of committee reassignments, one or more Republicans will be appointed to the committee.

Senator Murray Will Head Health Subcommittee

Reorganization of the Senate in January will make Senator James E. Murray (Democrat) of Montana chairman of the health subcommittee of the Senate's Committee on Labor and Public Welfare. Chairman of the full committee will be Senator Elbert D. Thomas (Democrat) of Utah. The reorganized health subcommittee, which will handle the bulk of medical and public health legislation to be considered by the Senate—including federal health insurance bills—probably will be composed of Murray, Pepper and Hill, Democrats, and Smith and Donnell, Republicans. Ball of Minnesota is the only member of this committee who was an election casualty.

McCarran and Rooney Due to Become Chairmen

Prospective chairman of the Senate Appropriations Subcommittee which will be in charge of the annual budget for the Federal Security Agency (which includes the U. S. Public Health Service, the Food and Drug Administration and the Social Security Administration) is Senator Pat McCarran (Democrat) of Nevada. He will replace the Republican incumbent, Senator William F. Knowland, of California. His "opposite number" in the House is expected to be Representative John J. Rooney (Democrat) of New York, who would replace Representative Frank B. Keefe (Republican) of Wisconsin.

Other committees, chiefly Labor and Public Welfare in the Senate and Interstate and Foreign Commerce in the House, are responsible for enabling legislation on federal participation in public health, subsidization of professional education, medical research and related programs. But it is the respective appropriations committees which hold the power on the amount of money that shall be expended on them.

Military Research Group on Field Inspection Trip

Accompanied by Army, Navy and Air Force staff assistants, members of the Research and Development Board's medical sciences committee departed October 26 for a ten-day air tour of military medical research facilities in North Carolina, Florida, Louisiana, Texas and Kentucky. Dr. Francis G. Blake, committee chairman, headed the party. Other members included Drs. Joseph F. Sadusk Jr., executive secretary, Lowell T. Coggeshall, John S. Lockwood, Wallace O. Fenn, James E. McCormack and William H. Fitzpatrick. Among those in the military contingent were Brig. Gen. George E. Armstrong, Deputy Surgeon General of the Army; Capt. W. P. Dana, head of the research division in the Bureau of Medicine and Surgery, Navy Department, and Brig. Gen. John M. Hargreaves, Deputy Air Surgeon. Installations which the group was scheduled to visit included the Naval Medical Research Laboratory at Camp Lejeune, N. C.; Orlando, Fla., entomologic laboratories of the Department of Agriculture; the Naval School of Aviation Medicine at Pensacola, Fla.; Randolph Field School of Aviation Medicine; Army Medical Field Research Laboratory at Fort Knox, Ky., and Eglin Field, Fla.

Nearly $1,000,000 in Research Grants Approved by Federal Council

A total of ninety-four medical research grants, aggregating $931,605, has been approved by the National Advisory Health Council, according to a tabulation obtained from the Division of Research Grants and Fellowships, National Institutes of Health. Favorable action on the applications, comprising thirty-eight continuation grants and fifty-six new projects, was taken at the October 22-23 meeting of the advisory council.

Tuberculosis received the largest share of the allocations—seven projects totaling $128,865. Investigations on metabolism and endocrinology ranked second, with $113,222 for sixteen separate investigations. Next in order were pathology, $81,390; physiology, $75,137, and biochemistry and nutrition, $69,437. Lesser amounts were approved for investigations in antibiotics, bacteriology, cardiovascular diseases, dental problems, gerontology, hematology, pharmacology, public health methods, radiobiology, sanitation, surgery, syphilis, tropical disease and virus and rickettsial infections.

Of the twenty fields of research with which the National Advisory Health Council is concerned, only one—malaria—was not represented by an award. Recipients of the grants will be announced later by the U. S. Public Health Service.

$455,715 in Federal Medical Research Grants Approved

Thirty-seven grants, totaling $455,715, for research in medical and related fields have been approved by the U. S. Public Health Service, on recommendation of the National Advisory Health Council. Recipient of the largest award, $64,620, was Dr. Esmond R. Long, for investigations in streptomycin therapy of tuberculosis. Among other recipients were Northwestern University Medical School, $48,000, for research in rheumatic fever; Duke University, $30,326, for work on relationship between diet and hypertensive vascular and renal diseases; Western Reserve, $27,884, for revascularization of the heart, and New York University, $27,985, for research in biologic aspects of schistosomiasis.

Next meeting of the National Advisory Health Council will be on February 18. Applications for research grants, to be considered at this meeting, must be received no later than December 1 by the National Institutes of Health (Division of Research Grants and Fellowships), Bethesda, Md.

Dr. Andrews Leaves on Special Malaria Mission to Iran

His mission reflecting the importance attached by the federal government to fostering of friendly relations with the Middle East, Dr. Justin Andrews left Washington late in October to lay the groundwork for an intensive malaria eradication program in Iran. According to the State Department, his services were requested by the Iranian government, which is anxious over extremely high incidence of malaria in the Azerbaijan region.

Dr. Andrews is head of the scientific section of the Communicable Disease Center operated by the U. S. Public Health Service at Atlanta, Ga. During World War II he served in the Army as a malariologist, first in the Mediterranean area and later in the Southwest Pacific.

Coming Medical Meetings

American Medical Association Interim Session, St. Louis, Municipal Auditorium, Nov. 30-Dec. 3. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Conference of State Secretaries and Editors, St. Louis, Hotel Statler, Nov. 28-29. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

National Medical Public Relations Conference, St. Louis, Hotel Statler, Nov. 27. Mr. Lawrence W. Rember, 535 N. Dearborn St., Chicago 10, Director.

American Academy of Dermatology and Syphilology, Chicago, Palmer House, Dec. 5-9. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, Secretary.

American Academy of Pediatrics, Atlantic City, Chalfonte-Haddon Hall, Nov. 20-23. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American Society of Tropical Medicine, New Orleans, Roosevelt Hotel, Dec. 5-9. Dr. Frederick J. Brady, National Institute of Health, Bethesda 14, Maryland, Secretary.

Association for Research in Nervous and Mental Diseases, New York, Waldorf-Astoria Hotel, Dec. 10-11. Dr. Clarence C. Hare, 700 W. 168th St., New York 32, Secretary.

Eastern Section, American Federation for Clinical Research, Philadelphia, Temple University School of Medicine, Dec. 4. Dr. J. Edward Berk, Temple University School of Medicine, Philadelphia, Chairman.

Puerto Rico, Medical Association of, Santurce, Dec. 10-12. Dr. J. Basora Defillo, Box 3866, Santurce, Secretary.

Radiological Society of North America, San Francisco, Dec. 5-10. Dr. Donald S Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Southern Psychiatric Association, Dallas, Texas, Hotel Adolphus, Dec. 6-7. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southern Surgical Association, White Sulphur Springs, W. Va., Dec. 7-9. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Western Surgical Association, St. Louis, Dec. 2-4. Dr. Warren H. Cole, 1853 W. Polk St., Chicago 12, Secretary.

GOVERNMENT SERVICES

ARMY

COMMITTEE ON CHEMICAL WARFARE

The Research and Development Board of the National Military Establishment announces the appointment of Dr. W. Albert Noyes Jr., professor of chemistry, University of Rochester, as chairman of the recently established Committee on Chemical Warfare. The Committee will work with the Office of Civilian Defense Planning, National Military Establishment. Professor Arthur C. Cope, chairman, department of chemistry, Massachusetts Institute of Technology, has been appointed alternate to Dr. Noyes; others on the Committee are H. F. Johnstone, professor of chemical engineering, University of Illinois, with A. P. Colburn, University of Delaware, as his alternate; and Robert C. Swain, Vice President of the American Cyanamide Company, with R. T. Major, Vice President of Merck and Company, as his alternate. In addition to those named, members from the three military departments will serve on the Committee, the acting executive director of which is H. I. Cole, Ph.D., who served with the Chemical Warfare Service in World War I and in the Chemical Corps, U. S. Army, in World War II.

TRAINING IN CIVILIAN INSTITUTIONS

The following medical department officers have been accepted for training in the civilian institutions indicated: Colonel Charles J. Farinacci, Cornell University, cytologic diagnosis of cancer; Lieutenant Horace W. Shreck, Bellevue Hospital, New York, ophthalmology; Captain Charles I. Hamilton Jr., Franklin Hospital, San Francisco, clinical medicine; and for intern training as first lieutenants Sidney L. Brown, San Francisco City and County Hospital; Joseph C. Cullina, Gallinger Municipal Hospital, Washington, D. C.; Jack D. Fetzer, Hermann Hospital, Houston, Texas; John M. Kohl, Wilkes-Barre General Hospital, Wilkes-Barre, Pa.; Alfred Lubart, Morrisania City Hospital, New York; Tom E. Nesbitt, University Hospital, Ann Arbor, Mich.; John Thomas Olive, St. Joseph's Hospital, Kansas City, Mo., and Robert G. Richards, White Memorial Hospital, Los Angeles.

EXHIBIT AT CENTENNIAL CELEBRATION

At the Centennial Celebration of the establishment of Fort Bliss at El Paso, Texas, November 3-7, the Army Medical Illustration Service of the Army Institute of Pathology presented an exhibit made up of thirteen panels, one of which was a photomontage of "The Healthiest Soldier in the World." Five other panels supported the theme by showing how a recruit gains through preventive medicine, expert medical attention and Army service, and how the country profits from Army research and the Army training program for medical personnel. In the center of the exhibit a section was devoted to William Beaumont, an Army medical officer and America's first experimental physiologist, whose observations on the Canadian trapper Alexis St. Martin led to the modern studies on digestion and dietetics.

NAVY

COURSE IN AVIATION MEDICINE

Regular and reserve medical officers up to and including the rank of lieutenant commander may make application for the next course in aviation medicine to be held at the school of Aviation Medicine and Research, Pensacola, Fla., beginning Jan. 17, 1949. Instruction will be given in such subjects applicable to aviation medicine as cardiology, ophthalmology, otolaryngology and applied aviation physiology. Students will then be assigned to flight indoctrinal training and ground school work, after which successful students will be designated Naval flight surgeons. Applications must reach the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., prior to Dec. 10, 1948.

NEW NAVY INTERNS

The following recent graduates have accepted commissions as lieutenants (jg) in the Medical Corps Reserve for internship in civilian institutions under the Navy Medical Intern training Program: George F. Batten, Chelsea, Mass., to the Naval Hospital, Bethesda, Md.; Robert M. Clark, Canton, Ohio, to Mercy Hospital in that city; Leonard O. Congit, Los Angeles, to Queen of Angels Hospital in that city; Robert W. Hoellwarth, Lodi, Calif., to DePaul Hospital, St. Louis; Harold D. Lankford, St. Louis, to St. Louis City Hospital; Joseph J. Miller, Reinerton, Pa., to Reading Hospital, Reading, Pa.; David P. Morris Jr., Detroit, to Harper Hospital, Detroit; Eugene R. Odou, Los Angeles, to Los Angeles County Hospital in that city; David J. Seel, Bradenton, Fla., to Charity Hospital, New Orleans; Jack D. Stringham, Salt Lake City, to Latter Day Saints Hospital in that city; Robert B. Tator, New Haven, Conn., to Baylor University Hospital, Dallas, Texas; Wyman C. Tremblay, Hollywood, Calif., to Queen of Angels Hospital in Los Angeles; Mark M. Walter Jr., Lansdowne, Pa., to Philadelphia General Hospital, and Francis P. Weyrens, Hebron, N. D., to St. Mary's Group Hospitals, St. Louis.

OFFICERS REQUEST ACTIVE DUTY

The following reserve medical officers have requested active duty in the Navy: Comdr. William M. Cason, Atlanta, Ga.; Lieut. Comdr. Ulysses S. Geiger, North English, Iowa; Lieut. Charles E. Weber, Rochester, N. Y., and Lieutenants (jg) Victor G. Benson, Soldiers Grove, Wis., and Jerome Imburg, Richmond, Va.

PUBLIC HEALTH SERVICE

CLEARINGHOUSE FOR CHILD LIFE RESEARCH

The Children's Bureau in Washington, D. C., has established a clearinghouse for research in child life in response to numerous requests for a center that would promote interchange of information on current research in fields affecting child life. The clearinghouse will contact investigators for reports of studies in progress. It will not attempt to summarize or indicate the conclusions of research projects but will furnish accounts of the nature of the projects as reported by individuals and organizations. The clearinghouse grew out of a series of conferences held to review what is going on in research in child life. Further information may be obtained from Clara E. Councell, Director, Clearinghouse, Children's Bureau, Washington 25, D. C.

DR. EAGLE RETURNING FROM AFRICA

Dr. Harry Eagle, chief, research branch, National Cancer Institute, is returning from Africa where for several weeks he studied the effects of using arsenical compounds for sleeping sickness, a treatment which he helped develop in 1944-1945. Use of para-arsenosophenylbutyric acid for trypanosomiasis was developed by Dr. Eagle in collaboration with the Sleeping Sickness Services of the Belgian Congo, French Equatorial Africa, French West Africa, the Gold Coast, Nigeria, and the Firestone Plantation in Liberia. At that time Dr. Eagle was head of the U. S. Public Health Service Venereal Disease Research and Postgraduate Training Center located at Johns Hopkins Hospital, Baltimore. An account of this work appears in *Public Health Reports,* July 12, 1946, page 1019.

MEETING OF QUARANTINE OFFICERS

All medical officers in charge of the major quarantine stations of the Public Health Service, those in charge of medical examinations of visa applicants in Europe and Montreal, and representatives of the nonmedical quarantine inspection officers and sanitary inspectors held their first meeting in Washington September 20-24. The conference agreed on standard measures to modernize quarantine further to meet the demands of international commerce while still affording adequate protection against importation of disease. They voted unanimously to retain the present smallpox immunization requirements and to continue the rabies control work. Technical information was furnished by representatives of several organizations with work related to that of the Foreign Quarantine Division. The chief of the Canadian Quarantine and Immigration Medical Service was present as an observer and collaborator.

DR. DOULL TO DIRECT LEPROSY RESEARCH

The Federal Security Administrator announces that Dr. James A. Doull, chief, Office of International Health Relations, Public Health Service, has been detailed to the American Leprosy Foundation (Leonard Wood Memorial) as Director of Research with headquarters in Washington. Studies will be made on the epidemiology of leprosy and methods of treatment. The Foundation is now supporting epidemiologic studies in the Philippines and a special bacteriologic laboratory at Harvard Medical School. Dr. Doull was chairman of the medical advisory board, American Leprosy Foundation from 1940 to 1943. He formerly was a professor at Western Reserve University School of Medicine, and served as medical consultant to UNRRA and the Foreign Economic Administration. He joined the Public Health Service in 1943.

Dr. L. L. Williams Jr., medical director, will succeed Dr. Doull as chief, Office of International Health Relations. He has for twenty-six years been a specialist in malaria control research. He was head of the malaria commission to the China-Burma Highway and at the start of the war organized malaria control in areas of camps and war industries. Detailed to the Army, he was a malariologist in the North African Theater of Operations.

REGULAR CORPS APPOINTMENT AS SANITARIAN

Examinations for appointment in the Regular Corps in the grades of assistant sanitarian and senior assistant sanitarian will be held in the near future. An applicant for the assistant grade must be a citizen of the United States at least 21 years of age, have a bachelor's degree from a school of recognized standing, in one or more fields which are related to milk and food sanitation, have a master's degree from an approved school in public health or in a related science, and have had at least seven years of educational (exclusive of high school) and professional training and experience. An applicant for the senior assistant grade in addition must have had at least ten years of educational (exclusive of high school) and professional training and experience.

The written examination for both grades will be in bacteriology, chemistry, physics, epidemiology, administration and their relation to environmental sanitation in general and to milk and food control in particular. Information may be obtained from the Surgeon General, United States Public Health Service, Washington 25, D. C.

MISCELLANEOUS

NINETEEN ATOMIC RESEARCH PROJECTS

The Atomic Energy Commission has selected nineteen research projects in biology and medicine proposed by nongovernmental institutions in ten states for financial support. These are in addition to thirty-eight projects announced last May by the Commission. Following is a list of the institutions in which this research will be conducted, the subject of the research, and the director of the project:

COLORADO

- University of Colorado, Boulder
  - John R. Lacher—Study of Relationships Between Chemical Structure, Physical Characteristics and Biologic Activity in the Intermediate Metabolism of Nucleic Acid Derivatives
  - Theodore T. Puck—Study of the Radiation Chemistry of Bacteriophage Invasion and Reproduction in Host Cells

ILLINOIS

- Northwestern University, Evanston
  - J. Roscoe Miller—Establishment of a Radioisotopic Unit for Instruction, Research and Therapy

MASSACHUSETTS

- Massachusetts Institute of Technology, Cambridge
  - Robley D. Evans—Radiomedicine Research
- Arnold Arboretum, Harvard University, Boston
  - Karl Sax—Dosage Curve Under Varying Conditions of Time and Intensity of Radiation

NEW YORK

- College of Physicians & Surgeons, Columbia University, New York
  - David Nachmonsohn—Effects of Exposure to Radioactive Materials and to X-Ray Irradiation on Nerve Tissue
- N. Y. Post Graduate Hospital, New York
  - Marion B. Sulzberger—Skin Changes Produced by Low-Voltage Roentgen Ray Irradiation

NORTH CAROLINA

- N. C. University, Chapel Hill
  - H. D. Bruner—Measurement of Volume of Flow of Blood in the Kidney and Level of an Unanesthetized Man by Means of Radioisotopic Procedure

OHIO

- Ohio State University, Columbus
  - J. L. Morton—Establishment of Physical and Medical Principles in Use of Artificially Radioactive Cobalt 60 for Treatment of Cancer
- Western Reserve University, Cleveland
  - H. L. Friedell—Medical and Biologic Research on Toxicologic Effects of Thorium and the Comparative Effects of Various Types of Internally Distributed Ionizing Particles
  - Harland G. Wood—Intermediary Metabolism on Carbohydrates by Bacteria

OREGON

- University of Oregon, Eugene
  - Arnold L. Soderwall and Paul Risley—Localization of Radioactive Isotopes in Reproductive and Germinal Tissues During Periods of Quiescence and Activation
- Oregon State College, Corvallis
  - Joseph S. Butts—Mode of Action of 2-4-Dichlorophenoxyacetic Acid as Studied with the Use of C-14
  - V. H. Cheldelin and B. E. Christensen—Study of Vitamin-Amino Acid and Carbohydrate-Amino Acid Relationships Using C-14 as a Tracer Substance
- University of Oregon Medical School, Portland
  - Edward S. West—Degradation of Radioactive Cholesterol Fatty Acids and Ketone Bodies in the Animal Body

TEXAS

- Baylor University, Waco
  - Joseph H. Gast—Chemistry and Metabolism of Some Sulfur Oxides
- University of Texas, Austin
  - Jack Myers—Biologic Accumulation of Inorganic Materials by Algae

WASHINGTON

- University of Washington Medical School, Seattle
  - Robert H. Williams—Biologic Effects of Radioactive Sulphur

WISCONSIN

- University of Wisconsin Medical School, Madison
  - James A. Miller—Labeled Azo Dye Research

These projects will be administered by the Office of Naval Research under the joint program of support of fundamental scientific research.

ASSIGN ATOMIC ENERGY FELLOWS

Nine medical officers from the armed forces, one from the Public Health Service, and one from the British Royal Navy have been assigned to training centers for study under the Atomic Energy Commission fellowship program. The centers to which these officers have been assigned for six months are at the University of Colorado, Denver; Duke University, Durham, N. C., and Reed College, Portland, Ore. Following this six months' course in basic training, the fellows from the armed forces and Public Health Service are expected to be assigned to Atomic Energy Commission installations for field training. The medical officers assigned are as follows: Captain Donald E. Dement, U.S.N.; Captain Paul M. Hoot, U.S.N.; Surgeon Commander Dennis A. Hovenden, British Royal Navy; Lieut. Col. Clinton C. Maupin, U.S.A.; Lieut. Col. John H. Rust, U.S.A.; Lieut. Comdr. Elmer R. King, U.S.N.; Lieut. Comdr. Peter S. Kwiatkowski, U.S.N.; Capt. Edward A. Langdon, U.S.A.; Lieut. (jg) Garner L. Lewis, U.S.N.; First Lieut. Ellis Oster, U.S.A.; Dr. Samuel C. Ingraham, Surgeon, U.S. Public Health Service.

PHYSICIANS SEPARATED FROM SERVICE

ARMY MEDICAL CORPS OFFICERS RECOMMENDED FOR/OR RELIEVED FROM ACTIVE DUTY

Alabama

Brock, Jack	New Brockton
Clayton, Orville W.	Fort Payne
Fargason, Crayton C. Jr.	Dadeville
Hanks, Boyce L.	Monroe
Kennamer, Samuel R.	Montgomery
Lamb, Robert H.	Troy
Mason, Robert H.	Russellville
Nabers, Hugh C.	Birmingham

Arkansas

Bell, Henry Grady Jr.	Little Rock
Birdsong, Karl K.	Shiloh
Brogdon, Paul P. Jr.	Springdale
Clardy, Edgar K.	Hot Springs
Dicksinson, Rodger C.	Horatio
Leidinger, Karl J. Jr.	Monticello
Regnier, George G.	Parkdale
Scruggs, Joe Bartie Jr.	Little Rock
Silverblatt, Charles W.	Osceola

California

Aagaard, Carl M. J.	San Francisco
Connor, Harold L.	San Francisco
Jonte, Donald M.	Stockton
Kay, Fred M.	W. Los Angeles

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

COLORADO

Committee to Review Newspaper Medical Advertising.—The Medical Society of the City and County of Denver, at the request for assistance from the advertising director of the *Denver Post,* has appointed a committee to review medical advertising for Denver papers. Members of the committee are Drs. Richard W. Whitehead, chairman, Roy L. Cleere, Maurice Katzman, Albert E. Evans and Herman S. Maul. The committee is to work in cooperation with the public policy committee of the medical society.

Expand Epilepsy Program.—Through a $5,000 annual grant from the Colorado Society for Crippled Children and Adults, the University of Colorado Medical Center, Denver, has expanded its epilepsy program. Dr. Harriot H. Hunter is director of the university's epilepsy clinic. The grant provides for a director, honorariums for two medical assistants, the services of a social worker, and for administrative services and supplies. Early projects include a registry of epileptics, an adult training program and a workshop to provide group therapy for parents as well as patients.

DELAWARE

State Medical Election.—At the annual September meeting of the Medical Society of Delaware, Dr. Mesrop A. Tarumianz, Farnhurst, was elected president for 1949; Drs. Gerald A. Beatty, Wilmington, secretary; Winfield W. Lattomus, Wilmington, treasurer, and James Beebe, Lewes, delegate to the American Medical Association, with Clyde C. Neese, Wilmington, as alternate.

ILLINOIS

Postgraduate Conference in Pekin.—The Illinois State Medical Society has arranged a conference for the Fifth Councilor District at the Pekin Country Club, Pekin, December 9. The speakers, all of Chicago, will be:

William T. Carlisle, Forewarning and Forearming in Obstetrics.
Chauncey C. Maher, Management of Cardiac Patients Pre- and Post-Operatively.
H. William Elghammer, Advances in Pediatrics.

At the dinner Dr. Percy E. Hopkins, Chicago, will discuss "Voluntary Prepayment Medical Care" and Dr. Chester C. Guy, Chicago, "Bleeding Peptic Ulcer."

Chicago

Lecture on Reconstruction of Face.—Sir Archibald McIndoe, chief of plastic surgery for the Royal Air Force during World War II, lectured on "Total Reconstruction of the Face Following Burns" at the University of Illinois College of Medicine November 10. Sir Archibald is senior plastic surgeon at St. Bartholomew's Hospital in London and surgeon at Queen Victoria Hospital in East Grinstead.

Dr. Lederer to Aid in Mexico's Hearing Program.—Dr. Francis L. Lederer, professor of otolaryngology and head of the department at the University of Illinois College of Medicine, has left for Mexico, where he will aid medical officials in formulating a national program for the hard of hearing. At the invitation of the Mexican undersecretary of health and welfare, he will travel through that country to conduct a survey of hearing and speech needs.

Survey of Cancer.—The Committee on Chicago-Cook County Health Survey reports that a questionnaire sent to doctors and hospitals in the city has indicated that more than 7,000 persons died of cancer and at least 15,000 new cases of cancer appeared in Chicago last year. The questionnaire was answered by 90 per cent of the physicians and 96 per cent of the hospitals queried. The next project will be to survey the problem of cancer in industry.

Dr. Lewy Receives Traditional Cane.—At the November meeting of the Chicago Laryngological and Otological Society Dr. Alfred Lewy was presented with the traditional cane of the society, which was started in circulation by the late Dr. Joseph C. Beck. It is held as the temporary property of the senior living member of the society and contains in its handle models of several otolaryngologic instruments. The late Dr. George E. Shambaugh was the preceding recipient of the cane.

Allergy Research Unit.—Northwestern University has established a research unit for allergy studies in the new allergy research laboratory under the general direction of Dr. Samuel Feinberg, chief of the division of allergy. Laboratory research is being directed by Dr. Saul Malkiel, newly appointed assistant professor of medicine at Northwestern. Initial support of the allergy research laboratory was implemented by grants from the U. S. Public Health Service and several pharmaceutical manufacturers.

Dr. Moruzzi at Northwestern University.—Dr. Giuseppe Moruzzi, Italian neurophysiologist, has been appointed to Northwestern University Medical School for a year of research by the Rockefeller Foundation, which last year established an annual visiting professorship in the university's Institute of Neurology. Dr. Moruzzi is director of the Institute of Human Physiology at the University of Parma, Italy, and professor of physiology in its medical school. He will devote most of his research to the physiology of the brain and the functional relation of the cerebellum to the cerebral cortex.

Five Illinois Professors Retire.—Five members of the faculty of the University of Illinois College of Medicine retired September 1, having reached retirement age: Dr. Selim W. McArthur, clinical professor of surgery; Dr. Clifford G. Grulee, Rush, clinical professor of pediatrics and former head of the department at Presbyterian Hospital; Dr. James H. Mitchell, Rush, clinical professor of dermatology and former head of the department of dermatology and syphilology at Presbyterian Hospital; Dr. Daniel B. Hayden, clinical professor of otolaryngology (Rush) and former head of the department at Presbyterian Hospital, and Dr. Morris Braude, clinical associate professor of psychiatry (Rush).

Certificates of Merit and Appreciation.—At a reception at the home of Chancellor Robert M. Hutchins of the University of Chicago, November 2, thirteen scientists of the university faculty were cited for their contributions to the war effort in presidential certificates of merit and of appreciation. Admiral Cary Jones, commandant, Ninth Naval District, and Lieutenant General Stephen J. Chamberlin, commanding general, Fifth Army, made the presentations. Among those receiving the certificate of appreciation were the following from the Toxicity Laboratory: Dr. Franklin B. McLean, first director of the Toxicity Laboratory; Dr. William B. Bloom, professor of anatomy; William L. Doyle, second director of the laboratory and associate professor of anatomy, and Dr. Eugene M. K. Geiling, chairman of the department of pharmacology. Among other faculty members receiving certificates of appreciation were William H. Taliaferro, Ph.D., chairman of the department of bacteriology and parasitology; Dr. E. S. Guzman Barron, associate professor of biochemistry, and Paul A. Weiss, professor of zoology. Among other Chicago scientists not on the faculty of the University of Chicago to be thus honored was Dr. Sidney O. Levinson, executive director of Michael Reese Research Foundation.

IOWA

Personal.—Dr. Hunter H. Comly was appointed assistant professor of pediatrics in the department of psychiatry at the State University of Iowa College of Medicine, Iowa City, effective September 1.

Dr. Rovenstine to Address Linn County Society.—At the December 16 meeting of the Linn County Medical Society in Cedar Rapids, Dr. Emery A. Rovenstine, New York, will speak on "Intravenous Use of Procaine and Its Derivatives." Drs. Stuart C. Cullen, Iowa City, and Florence D. Johnston, Cedar Rapids, will lead the discussion.

KANSAS

Refresher Course in Obstetrics and Gynecology.—A refresher course in obstetrics and gynecology will be presented December 6-8 at the University of Kansas Medical Center, Kansas City. Besides faculty of the University of Kansas, guest instructors will be Drs. John H. Moore, Grand Forks, N. D.; Lucien R. Pyle, Topeka; Lawrence M. Randall, Rochester, Minn., and Ray A. West, Wichita.

KENTUCKY

Hospital Advisory Board.—Dr. E. Bruce Underwood, Louisville, state health commissioner, has appointed five men as advisers on the administration of a state hospital plan. They are Dr. F. Guy Aud, Louisville, past president of the Kentucky State Medical Association; Dr. John W. Moore of the University of Louisville School of Medicine; Lee R. Curtis, Louisville, an attorney; Dr. Joshua B. Lukins, Louisville physician, and Mr. S. A. Ruskjer, former president of the Kentucky Hospital Association. They will advise Dr. Underwood on the distribution of $500,000 this year and the same amount next year to Kentucky hospitals eligible for this state money.

LOUISIANA

Personal.—In honor of Dr. Urban Maes, New Orleans, at Touro Infirmary where he served for fifty years, a bronze plaque was recently unveiled. Charity Hospital also honored Dr. Maes in a like manner for forty-three years of service to that institution.

Dr. Lippard Goes to University of Virginia.—Dr. Vernon W. Lippard, dean since September 1946 of the Louisiana State University School of Medicine, New Orleans, has accepted the deanship of the University of Virginia Department of Medicine, Charlottesville, effective Feb. 1, 1949. Dr. Lippard is a graduate of Yale University School of Medicine, 1929. Before going to Louisiana he was associate dean of the Columbia College of Physicians and Surgeons, New York.

MINNESOTA

Residual Beneficiary of Doctor's Estate.—The University of Minnesota Medical School, Minneapolis, has been named a residual beneficiary of the $150,000 estate of the late Dr. James S. Reynolds of Minneapolis. The estate is to be placed in trust for Dr. Reynold's sister, on whose death the remainder of the estate is to be used as a scholarship fund in the medical school.

Establish Rehabilitation Center.—A rehabilitation center has been established at 279 Rice Street, St. Paul. A medical advisory board of seven doctors appointed by the Ramsey County Medical Society guides the medical policies of the center, the aims of which are prevention of unnecessary handicaps, restoration of function if possible, use of residual function and adjustment of patient to any residual disability. The three sponsoring agencies are the Minnesota Society for Crippled Children and Adults, Junior League of St. Paul, and the Wilder Charity.

NEW YORK

Food Service Training School.—A Food Service Training School has been opened at Hudson River State Hospital, Poughkeepsie, for instruction of institution employees and the development of high standards of food preparation and service in state institutions. The first class began October 11.

Eastman Memorial Lecture.—De René J. Dubos, Sc.D., a member of the Rockefeller Institute for Medical Research, New York, delivered the Eastman Memorial lecture on "Cellular Structures Concerned in the Pathogenesis of Tuberculosis" at the University of Rochester Medical School amphitheater November 19.

Mental Health Research Clinic at Buffalo.—The State Department of Mental Hygiene, in cooperation with the University of Buffalo School of Medicine, will set up a mental health research clinic in alcoholism at two leading Buffalo hospitals. The state department has made a grant to the clinic to implement in part a demonstration program.

Postgraduate Instruction.—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged the following postgraduate instruction programs: For the Oswego County Medical Society Dr. L. Maxwell Lockie, Buffalo, spoke on "Management of Arthritis" on November 16, 8:30 p. m., at the Elks Club, Fulton. On November 17 Dr. Locke L. Mackenzie, New York, addressed the members of the Fulton County Medical Society on "Use of Cell Smears in the Early Diagnosis of Cancer" at the Hotel Johnstown, Johnstown, 8:30 p. m.

New York City

Society News.—The Division of Mycology of the New York Academy of Sciences recently heard Norman F. Conant, Ph.D., Duke University School of Medicine, Durham, N. C., lecture on sporotrichosis. At the inaugural meeting October 22, officers elected were Drs. Frederick Reiss, president, and Royal M. Montgomery, secretary.

Harvey Lecture.—Dr. George K. Hirst, chief, Division of Infectious Diseases, Public Health Research Institute of the City of New York, delivered the second Harvey Lecture of the current series at the New York Academy of Medicine on November 18, on "The Biological Significance of the Virus Hemagglutinins."

Dr. Brown Named Acting Chairman of Medical Board.—Dr. Samuel A. Brown, formerly president of the New York Academy of Medicine and dean emeritus of the college of medicine, has been named acting chairman of the board of trustees of the New York University—Bellevue Medical Center, succeeding the late Richard W. Lawrence, LL.D. The board was formed in May to direct the affairs of the new medical center, which includes, in addition to the college of medicine, the Institute of Rehabilitation, the Institute of Industrial Medicine and the University Clinic. The medical center is also responsible through its teaching faculty for a major portion of the medical care given at Bellevue Hospital. Dr. Brown is a graduate of the University Medical College (New York University), 1894.

Dr. Senn Goes to Yale.—Dr. Milton J. E. Senn, professor of pediatric psychiatry and director of the Institute of Child Development at Cornell University Medical College, has been appointed Sterling professor of pediatrics and psychiatry and director of the new Yale University Child Study Center. The center, which will include the Yale Clinic of Child Development, will help parents, teachers and others concerned with problems of children. It will contain a guidance nursery, film library and clinical resources to supply research and teaching mediums for students interested in growth, development, behavior and personality. Dr. Senn received his M.D. degree from the University of Wisconsin Medical School, Madison, in 1927. He was an assistant professor of pediatrics at Cornell University Medical College in 1939, and then was made associate professor of pediatrics in psychiatry. Last year he was promoted to professor and was made director of the Institute of Child Development.

OHIO

Dr. Brailsford's Lecture.—At a special meeting of the Academy of Medicine of Cleveland Dr. James F. Brailsford, Birmingham, England, lectured on "Radiographic Evidence of Metastasis in Malignant Diseases" November 19 at the Medical Library Auditorium, 8:30 p. m. Dr. Brailsford is radiologist to the Queen Elizabeth's Hospital and the Royal Hospital for Crippled Children.

Professor Birkeland Named Department Head.—Jorgen M. Birkeland, Ph.D., professor of bacteriology of the Ohio State University College of Medicine, Columbus, and a member of the department staff since 1935, was recently made chairman of the department succeeding William A. Starin, Ph.D., who retired this year as emeritus professor of bacteriology (The Journal, April 10, page 994).

Sunday Afternoon Health Lectures.—A series of Sunday afternoon health lectures, free to the public, are being presented by the Academy of Medicine of Cleveland through its Health Education Foundation at the Medical Library Auditorium, 4 p. m.

Nov. 28, Harry V. Paryzek, Cleveland, Medical Emergencies; Farrell T. Gallagher, Lakewood, Surgical Emergencies.

Dec. 5, Elliott P. Joslin, Boston, Diabetes Yesterday, Today and Tomorrow.

Jan. 30, Roy W. Scott, Cleveland, Medical Aspects of Heart Disease; Claude S. Beck, Cleveland, Surgical Aspects of Heart Disease.

PENNSYLVANIA

Tribute to Dr. Donaldson.—In tribute to his thirty years' service as secretary to the Medical Society of the State of Pennsylvania, Dr. Walter F. Donaldson, Pittsburgh, was presented by members of the society with a combination television-radio-phonograph at the recent centennial celebration in Philadelphia. Dr. Donaldson accepted the gift from the stage of the Academy of Music, Philadelphia, before more than 3,000 physicians, their wives and invited guests.

Philadelphia

Dr. DeLamater to Direct Research.—The department of dermatology and syphilology of the University of Pennsylvania School of Medicine has announced the appointment of Dr. Edward D. DeLamater as associate research professor. He will act as director of research in the department and develop a mycology laboratory. Dr. DeLamater, a graduate of Columbia University College of Physicians and Surgeons, New York, 1942, has recently served on the staff of the Mayo Clinic, Rochester, Minn.

Pittsburgh

Symposium on Lung Cancer.—The meeting of the Allegheny County Medical Society on November 16 at 9 p. m. was devoted to a symposium on cancer of the lung. Subjects presented were "Diagnostic Value of Bronchial Secretions in Cancer of the Lung," "Present Day Concepts of Lung Cancer" and "Diagnosis and Modern Management of Cancer of the Lung."

SOUTH CAROLINA

Public Health Appointment.—Dr. William H. Chapman of Bishopville has been employed to serve with the Division of Maternal and Child Health of the State Board of Health. His work will be principally educational with emphasis on child growth and better family life. He will be available as speaker to local medical groups. Dr. Chapman graduated from the University of Maryland School of Medicine, Baltimore, 1929, and in recent years has served in the Richland-Columbia Venereal Clinic.

Society News.—The South Carolina Society of Ophthalmology and Otolaryngology, meeting at Charleston, elected Dr. Pierre G. Jenkins of Riverland Terrace as president and Dr. Roderick Macdonald of Rock Hill, secretary-treasurer.——The North Carolina Eye, Ear, Nose and Throat Society elected Dr. James A. Harrill of Winston-Salem as president and Dr. MacLean B. Leath of High Point as secretary-treasurer.——Dr. John R. Harvin of Sumter was recently elected president of the South Carolina Pediatric Society, and Dr. J. Rufus Bratton of Rock Hill, secretary-treasurer.

UTAH

Dr. Lawrence to Direct Cancer Teaching Program.—Dr. Edwin A. Lawrence has been named professor of surgery (oncology), and director of the cancer teaching program in the University of Utah College of Medicine, Salt Lake City. Dr. Lawrence was formerly director of the Tumor Clinic at Yale University and more recently has been in practice in thoracic surgery in Salt Lake City. He is a graduate of Western Reserve University School of Medicine, Cleveland, 1935, and served on the resident surgical staff at New Haven Hospital, Conn. In 1938 he was made a W. H. Cushing fellow in surgery at Yale University and was instructor in surgery there.

VIRGINIA

College to Award Ph.D. Degree.—The Medical College of Virginia, Richmond, will add to the list of degrees it may award that of Doctor of Philosophy in medical and related sciences. The college will limit its selection of candidates for the degree to a few highly qualified persons interested in pursuing work in medical and related sciences.

Personal.—Dr. William T. Sanger, president, Medical College of Virginia, Richmond, has been appointed a member of the National Advisory Committee for the social work education study sponsored by the National Council on Social Work Education. Dr. Ernest V. Hollis is director of the study, for which the Carnegie Corporation has made a grant of $31,000. The study began on October 1 and is expected to be concluded June 30, 1949.

WISCONSIN

Annual Dearholt Day.—The University of Wisconsin Medical School, Madison, in cooperation with the Wisconsin Anti-Tuberculosis Association, is presenting the ninth annual Dearholt Day program in the Service Memorial Institutes Building, Madison, 3 p. m. November 23. Dr. William S. Middleton, dean of the medical school, will act as chairman. Dr. Edith M. Lincoln, New York, will speak on tuberculosis and children. Florence B. Seibert, Sc.D., Philadelphia, will discuss the component parts of tubercle bacilli and their relation to the tuberculin test. The program will be presented in Milwaukee both by the Marquette University School of Medicine and the Milwaukee County Medical Society on the preceding day and it will also service as a monthly meeting of the Dane County Medical Society at the Madison Club on Tuesday evening. Dr. Dearholt was executive secretary of the Wisconsin Anti-Tuberculosis Association from 1908 until his death in 1939.

WYOMING

State Medical Election.—The Wyoming State Medical Society installed Dr. George E. Baker, Casper, as president, and chose Dr. Dewitt Dominick, Cody, president elect; Dr. Peter M. Schunk, Sheridan, as treasurer, and Dr. Roscoe H. Reeve, Casper, delegate to the American Medical Association, with Dr. William A. Bunten, Cheyenne, as alternate.

ALASKA

Crippled Children's Headquarters.—The new $50,000 headquarters building of the Alaska Association of the International Society for Crippled Children was dedicated September 7 in Anchorage. Governor Ernest H. Gruening, Dr. Philip H. Moore, Mount Edgecumbe, orthopedic surgeon, Dr. C. Earl Albrecht, Juneau, territorial commissioner of health, and Dr. Catherine S. Sherwood, Juneau, director of the Crippled Children's Service of Alaska, took part. The center was completed this fall after three years of planning and fund raising to support the orthopedic hospital and the headquarters.

GENERAL

New Editor of Journal of Immunology.—Dr. Arthur F. Coca, Pearl River, N. Y., has resigned as editor of the *Journal of Immunology*, a position he had held since the foundation of the journal in 1916, and will now serve as associate editor. His successor is Dr. Geoffrey Edsall, Boston, director of the Antitoxin and Vaccine Laboratory of the State of Massachusetts.

Medical Mission to Colombia.—The Unitarian Service Committee has announced a medical mission to Colombia to be staffed by Drs. George H. Humphreys, New York, chairman; McKeen Cattell, New York; Rafael Domingues, Cleveland; Carney Landis, Ph.D., New York; Dr. Salvatore P. Lucia, San Francisco; Dr. Donovan J. McCune, New York, and Dr. Perry P. Volpitto, Augusta, Ga. Lectures will be given by the team on surgery, pharmacology, pathology, internal medicine, pediatrics, anesthesiology and psychology.

Southern Surgical Association.—The annual session of the Southern Surgical Association will be held at the Greenbrier Hotel, White Sulphur Springs, W. Va., December 7-9, under the presidency of Dr. Edwin P. Lehman, Charlottesville, Va. Among the subjects of papers to be presented are hyperthyroidism in children, surgical treatment of lesions of the suprarenal gland, partial hepatectomy with intrahepatic cholangiojejunostomy, amebic hepatic abscesses—prevention and treatment, and status of the surgical treatment of hypertension. The association dinner will be Wednesday evening at 7 o'clock, when Dr. Lehman will give the president's address.

Conference on Rehabilitation.—Community Organization for Rehabilitation will be the theme of the National Rehabilitation Association Conference at the Hotel Loraine, Madison, Wis., December 6-10. The program includes panel discussions on In What General Areas the Public and Voluntary Rehabilitation Agencies May Cooperate, Community Organization to Secure Adequate Legislation, Community Organization in Development and Use of Medical Rehabilitation Facilities and Community Organization for Public Relations. Requests for hotel reservations should be addressed to A. E. Towne, Rehabilitation Division, 320 State Office Building, Madison 2.

Society Elections.—The Southern Medical Association installed Dr. Oscar B. Hunter, Washington, D. C., as president, and chose Dr. Hamilton W. McKay of Charlotte, N. C., as president-elect at its recent convention in Miami, Florida. Cincinnati was selected as the convention city for 1949.——At the recent annual meeting of the American Society of Clinical Pathologists in Chicago October 12 to 15, Dr. Osborne A. Brines, Detroit, was installed as president, and Dr. James B. McNaught, Denver, was chosen president-elect. On the resignation of Dr. Alfred S. Giordano, South Bend, as secretary-treasurer, Dr. Clyde G. Culbertson, Indianapolis, was appointed to fill the unexpired term.

Van Meter Prize Award.—The American Goiter Association again offers the Van Meter Prize Award of $300 for the best essay on problems related to the thyroid gland. The award will be made at the annual meeting of the association in Madison, Wis., May 26-28, 1949, providing that essays of sufficient merit are presented. The competing essays should not exceed three thousand words and must be presented in English; a typewritten double-spaced copy must be sent to the Corresponding Secretary, Dr. Thomas C. Davison, 207 Doctors Building, Atlanta 3, Ga., not later than March 15, 1949. A place will be reserved on the program for presentation of the prize award essay by the author if it is possible for him to attend. The essay will be published in the annual proceedings of the association. This will not necessarily prevent its further publication in any journal selected by the author.

WHO Regional Organization.—The first World Health Organization's regional group was established at the conference of the South East Asia Regional Committee of the organization October 4 at New Delhi, India. It is the first such body among five or six to be set up in major geographic areas throughout the world as soon as the majority of countries in each area agree to participate. The regional organizations were authorized by the World Health Assembly last summer. Delegates from India, Siam, Ceylon, Burma and Afghanistan, together with observers from Nepal and French India as well as from the United Nations and its specialized agencies agreed on structure and program of the regional group. The World Health Organization's Executive Board will be requested to authorize by January 1 the establishment of the South East Asia Regional Office with Delhi proposed as its site.

Poliomyelitis Continues Epidemic in Some Areas.—According to the U. S. Public Health Service, the incidence of poliomyelitis continues above normal in a few areas although the decline is following the seasonal picture. A total of 830 cases was reported for the week ended November 4 as compared with

1,079 for the preceding week, 715 for the corresponding week in 1946, and a five year median of 489 for the week. Reported incidence declined in California from 206 to 198, in South Dakota from 121 to 58, in North Carolina from 42 to 29, in Ohio from 52 to 14, in Illinois from 41 to 21, in Wisconsin from 47 to 32 and in Iowa from 79 to 44. Incidence increased in Michigan from 39 to 52 and in Texas from 28 to 31. A total of 23,074 cases had been reported up to November 4, as compared with 22,377 in 1946, 9,195 in 1947 and a five year median of 11,952 for the corresponding period.

Ella Sachs Plotz Foundation.—The annual report of the Ellis Sachs Plotz Foundation for the Advancement of Scientific Investigation lists fifteen grants made during the current year to research workers in the United States, Europe and Asia. Grants are given in sciences related to medicine and usually will not exceed $500 but may be up to $1,000. Applications for the year 1949-1950 must be in the hands of the executive committee before April 15. Letters asking for aid must state definitely qualifications of the investigator and an accurate description of the research, the size of the grant requested and the specific use of the money to be expended. Applicants should state whether or not other foundations have been approached for financial assistance and what other sources of support are relied on for research. Applications should be sent to Dr. Joseph C. Aub, Massachusetts General Hospital, Fruit Street, Boston 14.

Dr. Armstrong Given Prentiss Award.—Dr. Donald B. Armstrong, New York, received the fifth Elisabeth S. Prentiss National Award in Health Education at the luncheon meeting of the American Public Health Association, Boston, November 9. Selection of Dr. Armstrong was based on his 1916 survey and study which led to the establishment of the Framingham, Mass., community health and tuberculosis experiment; his survey in 1920 that resulted in the first national health council, which he headed for several years; his work as secretary to the Milbank Memorial Fund Technical Board and his work as second vice president of the Metropolitan Life Insurance Company, New York, where he has been in charge of the health and welfare service for policy holders. The Prentiss Award was established in 1943 by the Cleveland (Ohio) Health Museum for encouragement of more and better work in the field of health education and is named in honor of the memory of the museum's first foundation benefactor, who also gave it its first home.

International Congress on Rheumatic Diseases.—The seventh International Congress on Rheumatic Diseases will be held at the Hotel Waldorf-Astoria, New York, May 30-June 3, 1949, under the sponsorship of the International League Against Rheumatism. The U. S. State Department will cooperate in issuing official invitations to various governments and rheumatism associations. Invited guests will be the members of the International League, the European League and Pan American League against Rheumatism with their constituent organizations. It is estimated that the program will include 80 to 100 papers, 70 invited discussants, 5 topics for panel discussions by about 30 participants and 15 clinics. Those who contemplate the presentation of papers should submit titles to the program committee for consideration before Jan. 1, 1949. Information may be obtained by writing Dr. Ralph Pemberton, 1901 Walnut St., Philadelphia, president of the International League, or Dr. J. Van Breemen, Keizersgracht 489 Amsterdam, Netherlands, secretary general.

Dr. Muller Delivers Sigma Xi Lectures.—Herman J. Muller, D.Sc., 1946 Nobel prize winner and professor of zoology at Indiana University, Bloomington, will present the results of his investigations on roentgen treatment of certain diseases in connection with the Sigma Xi Lectureship at colleges and universities in November, December and January. The lecture will be presented at the following institutions:

Nov. 15, Joint lecture to be held at Pullman, Wash., for the State College of Washington, Pullman, and the University of Idaho, Moscow.
Nov. 17, University of Washington, Seattle.
Nov. 19, Oregon State College, Corvallis.
Nov. 22, University of Oregon, Eugene.
Nov. 29, Stanford University, Palo Alto, Calif.
Dec. 1, University of California, Davis.
Dec. 3, University of Nevada, Reno.
Dec. 6, University of California, Berkeley.
Dec. 8, University of Utah, Salt Lake City.
Dec. 9, Brigham Young University, Provo, Utah.
Dec. 10, Utah State Agriculture College, Logan.
Dec. 13, Colorado A. and M. College, Fort Collins.
Dec. 15, Illinois Institute of Technology, Chicago.
1949
Jan. 18, The Abbott Research Laboratories, North Chicago, Ill.
Jan. 20, University of Wisconsin, Madison.
Jan. 21, Northwestern University, Evanston, Ill.

FOREIGN

Fund for Research on Rheumatism.—The Nuffield Foundation, a philanthropic organization in England, has received $1,800,000 from Captain Oliver Bird, wealthy Birmingham manufacturer, to promote research in the prevention and cure of rheumatism, according to the *Chicago Daily News.*

Textbooks on Nursing for Japan.—The American Red Cross, through the efforts of Edith Olson, Red Cross nursing consultant now in Tokyo, has given the Japanese Red Cross 130,000 pounds of paper stock which will be used to publish textbooks on home nursing, midwifery, nursing administration, public health and a reprinting of the "Nursing Procedure Manual." A portion of the paper has already arrived in Japan and production of the textbooks has begun.

Congress of Obstetrics and Gynecology.—The British Congress of Obstetrics and Gynaecology will be held in the Friends' Meeting House, Euston Road, London, July 1949. Papers will be presented by Dr. Joe V. Meigs, Boston, Mass.; Dr. Charles McIntosh Marshall, Liverpool; Dr. Gerald I. M. Swyer, London; Dr. Francis J. Browne, London, and Dr. Derrick M. Dunlop, Edinburgh. Owing to present difficulties in arranging hotel accommodations and travel, secretaries would like to have, by March 31, 1949 at the latest, the names of those who hope to attend.

Antituberculosis Drive in India.—The first nationwide BCG vaccination campaign in India, designed to lower the rate of tuberculosis among children and adolescents, was inaugurated in September at Madanapalle, near Madras. The program will be carried out jointly by the Indian health authorities and the World Health Organization, which last May sent a team of experts on tuberculosis to India at the government's request. Since transportation of BCG vaccine from Europe was unreliable, the World Health Organization also sent a pharmacologist to India to assist in setting up a laboratory which is now producing the vaccine. The number of tuberculosis cases in India is estimated at 2,500,000 annually out of a total population of 320,000,000, and the disease causes more than 500,000 deaths each year. The Indian program is part of the global antituberculosis campaign which the World Health Organization designated for priority action in 1949.

Marriages

Royal Green Jennings Jr., Thomasville, N. C., to Miss Treva Bullard Miller of Winston-Salem, October 2.

William Ralph Deaton Jr., Greensboro, N. C., to Miss Frances Kirksey of San Antonio, Texas, recently.

Michael Joseph Coffey, Belmar, N. J., to Miss Mary Jane Maas of Neptune at Asbury Park, September 18.

Charles M. Parker, Kelford, N. C., to Miss Anne A. Westphal at Fredericksburg, Va., September 4.

William Thomas Ellis, Schenectady, N. Y., to Miss Edna Margaret Murphy of Hamden, Conn., June 12.

S. Michael Erba, New Haven, Conn., to Miss Marcella La Reau Kytchen of Roanoke, Va., July 31.

Robert Lewis Nelson, New Berlin, N. Y., to Miss Catherine Rosemary Bertelli of Woodhaven, recently.

Ada Eleanor Biffar, Whitestone, N. Y., to Mr. Edward A. Ryan of Forest Hills, N. Y., recently.

Donald H. Glew Jr., to Mrs. Patricia Cummings Garrity, both of Washington, D. C., October 2.

Thomas Manley Flanagan to Miss Esther Ann Coyne, both of Norwich, N. Y., September 11.

John Thompson Prior, Syracuse, N. Y., to Mrs. Elizabeth Titus Troy of Binghamton, July 24.

Daniel H. Cannon, New Albany, Ind., to Miss Marilynn E. Carr of Delanco, N. J., October 2.

William H. Schlitzer, to Miss Helen Horan, both of Pottsville, Pa., in Philadelphia, July 17.

Antoni Mills Diehl to Miss Sybil Reid Bothwell, both of Newburyport, Mass., September 7.

Ira Deyo Le Fevre Jr., to Miss Helen Tate Rhodes, both of Schenectady, N. Y., July 24.

James N. Dewane to Miss Patricia Mullins, both of Menominee, Mich., September 11.

William E. Higgs to Mrs. Rae Myers, both of Cuba, N. Y., September 4.

Deaths

Abraham Myerson ⊕ Boston; born in Yanova, Russia, Nov. 23, 1881; Tufts College Medical School, Boston, 1908; served as clinical professor of psychiatry at the Harvard Medical School and the graduate school; professor of neurology emeritus at his alma mater; at one time on the faculty of St. Louis University School of Medicine; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member and formerly second vice president of the American Neurological Association; member of the American Psychiatric Association and the New England Society of Psychiatry; member and past president of the American Psychopathological Society; member of the Commission on Research in Mental Health, Commonweath of Massachusetts; served on the staffs of the McLean Hospital in Belmont and the Boston State, Beth Israel, Boston City, Boston Psychopathic, and Washingtonian hospitals; pathologist and clinical director of the State Hospital in Taunton, Mass., from 1914 to 1918; member of the Jewish Academy of Arts and Sciences; author of "Foundations of Personality," "Inheritance of Mental Diseases," "When Life Loses Its Zest" and other books; died September 3, aged 66, of cardiac decompensation.

William Payne Thompson, Princeton, N. J.; Columbia University College of Physicians and Surgeons, New York, 1924; formerly on the faculty of his alma mater; fellow of the American College of Physicians; member of the American Society for Clinical Investigation; president of the board of managers of the New Jersey State Hospital, Marlboro, and consultant at the Fitkin Memorial Hospital in Asbury Park; for many years on the staff of the Presbyterian Hospital; on the staff of the Mercer Hospital in Trenton; member of the board of trustees of the Trudeau (N. Y.) Sanatorium; died in the New York Hospital August 10, aged 50.

Edgar Ephraim Shifferstine ⊕ Tamaqua, Pa.; born Oct. 1, 1874; University of Pennsylvania Department of Medicine, Philadelphia, 1899; fellow of the American College of Surgeons; member of the American College of Hospital Administrators; director of clinics for rheumatic heart disease, state department of health; at one time surgeon in the U. S. Public Health Service reserve with the rank of major; president of the school board; served on the staffs of the Coaldale (Pa.) State Hospital and the Pottsville (Pa.) Hospital; director of the Tamaqua National Bank; died in the Abington (Pa.) Memorial Hospital August 22, aged 73, of carcinoma of the pancreas.

Charles Randolph Keith Swetnam ⊕ Prescott, Ariz.; born in Falmouth, Va., in 1882; Georgetown University School of Medicine, Washington, D. C., 1904; specialist certified by the American Board of Otolaryngology; past president of the Arizona State Medical Association and of the Yavapai County Medical Society; fellow of the American College of Surgeons; member of the American Academy of Ophthalmology and Oto-Laryngology and of the Pacific Coast Oto-Ophthalmological Society; a member and past president of the Prescott Community Hospital staff; died August 6, aged 66, of carcinoma of the prostate.

Wallace E. Belt, Dodge Center, Minn.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1889; died July 18, aged 91.

Harry Boyd-Snee, Los Angeles; Rush Medical College, Chicago, 1889; fellow of the American College of Surgeons; formerly practiced in South Bend, Ind., where he was on the staff of St. Joseph's Hospital; served during World War I; major, medical reserve corps not on active duty; died July 5, aged 79, of terminal bronchopneumonia.

Isham Lester Cummings ⊕ Ada, Okla.; Chicago College of Medicine and Surgery, 1912; on the staff of Valley View Hospital; died July 23, aged 58, of coronary occlusion.

Frank Daniel Elkavich ⊕ Troy, N. H.; McGill University Faculty of Medicine, Montreal, Canada, 1937; past president of the Cheshire County Medical Society; served during World War II; on the staffs of Quincy City (Mass.) Hospital and the Elliot Community Hospital in Keene, where he died July 27, aged 39, of injuries received in an automobile accident.

Isabella Maud Garnett, Evanston, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; formerly superintendent of Community Hospital, where she died August 23, aged 76, of uremia, hypertension and heart disease.

Arthur R. Hansen ⊕ Chicago; Chicago College of Medicine and Surgery, 1913; served during World War I; on the staff of the Henrotin Hospital, where he died September 11, aged 60, of hypostatic pneumonia following injuries received in a fall.

Charles Russel Hartsook ⊕ Wichita Falls, Texas; Medical College of Virginia, Richmond, 1904; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; past president of the Wichita County Medical Society; formerly councilor of the Third District of the State Medical Association of Texas; organizer of the Texas Society of Ophthalmology and Otolaryngology; affiliated with the Wichita General Hospital; died July 14, aged 74, of septicemia and myocarditis.

Euel Park Hathaway, Lawton, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1929; director of the city-county health department; died July 13, aged 45, of cirrhosis of the liver.

Frederick Henry Hollingsworth, Okmulgee, Okla.; Kansas City (Mo.) Medical College, 1901; formerly county clerk; died in Oklahoma City July 17, aged 74, of heart disease.

Theodore Holtan ⊕ Waterville, Minn.; Milwaukee Medical College, 1911; died August 22, aged 65, of heart disease.

Henry Pope Howard, Everett, Wash.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; member of the American Medical Association; fellow of the American College of Surgeons; died July 24, aged 81, of lobar pneumonia.

Charles Franklin Junkermann, Columbus, Ohio; the Hahnemann Medical College and Hospital, Chicago, 1889; died August 29, aged 86, of arteriosclerosis.

William Wolf Kahn, Van Nuys, Calif.; Baltimore University School of Medicine, 1896; died August 31, aged 81.

William Joseph Kennedy ⊕ Newark, Ohio; Georgetown University School of Medicine, Washington, D. C., 1905; on the staff of the Newark City Hospital; died July 16, aged 69, of carcinoma of the bladder.

Olin Arvin Kimble ⊕ Murdo, S. D.; Rush Medical College, Chicago, 1908; member of the local draft board during World War I; for many years city councilman; vice president of the Jones County Bank; died August 24, aged 70, of leiomyosarcoma.

Henry Eugene King ⊕ Fullerton, Neb.; John A. Creighton Medical College, Omaha, 1903; past president and secretary of the Nance County Medical Society; served during World War I; city physician; died in the Veterans Administration Hospital, Lincoln, August 25, aged 72, of heart disease.

Sterling Covert King, Watsontown, Pa.; Temple University School of Medicine, Philadelphia, 1922; member of the American Medical Association; served during World War I; affiliated with the Williamsport (Pa.) Hospital; died September 16, aged 52, of heart disease.

Edward Larkin ⊕ Washington, D. C.; Georgetown University School of Medicine, Washington, 1908; professor of clinical orthopedic surgery at his alma mater; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; served overseas during World War I; affiliated with the Veterans Administration Hospital in Mount Alto, and the Georgetown University Hospital, where he died August 18, aged 66, of arteriosclerosis.

Marshall Aiken Leach ⊕ Canonsburg, Pa.; Northwestern University Medical School, Chicago, 1940; president of the Canonsburg Borough Council; certified by the National Board of Medical Examiners; affiliated with Canonsburg General Hospital and the Pennsylvania Training School at Morganza; died in St. Francis Hospital, Pittsburgh, August 26, aged 36.

Eli Long, Cresco, Pa.; Columbia University College of Physicians and Surgeons, New York, 1896; member of the American Medical Association and the Medical Society of the State of New York; at one time on the faculty of the New York Post Graduate Medical School and Hospital, Columbia University; served during World War I; served on the staffs of Willard Parker and Presbyterian hospitals in New York; formerly medical director of the Bankers Trust Company; died August 3, aged 77, of coronary embolism.

George E. MacKinnon, Prentice, Wis.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1914; member of the American Medical Association; died in the Sacred Heart Hospital, Tomahawk, August 17, aged 61.

Edward Emmett McMahon, Omaha; John A. Creighton Medical College, Omaha, 1920; served as assistant professor of medicine at his alma mater; formerly medical director of Douglas County Hospital and on the staffs of Methodist, St. Joseph's, St. Catherine's and Immanuel hospitals; formerly affiliated with Veterans Administration Hospital in West Los Angeles; died August 19, aged 56, of coronary disease.

Edward Martin Miers, Mena, Ark.; University Medical College of Kansas City, 1910; member of the American Medical Association and the International College of Surgeons; president of the Polk County Medical Society; formerly on the staff of the Wesley Hospital in Kansas City, Mo.; died July 9, aged 62.

Isaac Julius Martinson, New York; University of Dorpat Faculty of Medicine, Russia, 1897; member of the American Medical Association; died August 24, aged 75, of coronary thrombosis.

Charles Carl Montano, Hartford, Conn.; Tufts College Medical School, Boston, 1935; member of the American Medical Association; served in the U. S. Public Health Service reserve attached to the Coast Guard from April 1943 to April 1946; affiliated with St. Francis and Hartford hospitals; died July 14, aged 38, of coronary thrombosis.

Oscar Nagel, Detroit; University of Michigan Medical School, Ann Arbor, 1932; member of the American Medical Association; served in the medical corps, Army of the United States, during World War II; died August 22, aged 48, of coronary heart disease.

Isaac DeWayne Nelson, River Rouge, Mich.; Meharry Medical College, Nashville, Tenn., 1945; interned at the Harlem Hospital in New York; certified by the National Board of Medical Examiners; on the staff of the Sidney A. Sumby Hospital; drowned while swimming near Amherstburg, Ontario, August 15, aged 29.

James Nisles Nesbitt, Gaffney, S. C.; University of Tennessee Medical Department, Nashville, 1889; member of the American Medical Association; died August 29, aged 81, of carcinoma of the colon.

Rea Parker ⊕ Smithfield, Va.; University College of Medicine, Richmond, 1908; also a graduate in pharmacy; past president and secretary of the Isle of Wight County Medical Society; county coroner and chairman of the county school board; active in Boy Scout work and in 1945 received the Silver Beaver; died August 2, aged 67, of coronary thrombosis.

Andrew B. Parr, Gonzales, Texas; Keokuk (Ia.) Medical College, 1892; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1905; died in Petaluma, Calif., August 10, aged 78.

Helen Myrtle Patton, Chicago; Northwestern University Medical School, Chicago, 1944; member of the American Medical Association; clinical assistant in the department of medicine at her alma mater; medical administrative assistant to the superintendent and a member of the hospital staff of Wesley Memorial Hospital, where she died August 4, aged 50.

John Birdsall Paul ⊕ Kansas City, Mo.; Kansas City (Mo.) Medical College, 1897; affiliated with the Research Hospital, where he died August 14, aged 77, of carcinoma with metastases.

Vincent Sylvester Pawelek Jr., ⊕ Houston, Texas; Baylor University College of Medicine, Dallas, 1943; interned at the Robert B. Green Memorial Hospital in San Antonio; served during World War II; killed instantly August 6, aged 29, in an automobile accident near Eunice, La.

Roy Gates Perham, Hasbrouck Heights, N. J.; Syracuse University College of Medicine, 1912; member of the American Medical Association; health officer and school physician for many years; on the staff of Hackensack (N. J.) Hospital; died August 4, aged 60, of cerebral hemorrhage.

Charles Pines, New York; University and Bellevue Hospital Medical College, New York, 1911; assistant clinical professor of dermatology and syphilology at his alma mater; on the staff of Bellevue Hospital; died in Mount Sinai Hospital August 21, aged 64, of coronary occlusion.

Mastin Lee Pipes, Moreland, Ky.; Hospital College of Medicine, Louisville, 1894; member of the American Medical Association; died August 14, aged 75, of injuries received when the automobile in which he was driving was struck by a train.

Lee Roy Plaugher ⊕ Denver; University of Colorado School of Medicine, Denver, 1927; served in France during World War I; affiliated with Porter Sanitarium and Hospital and St. Anthony Hospital, where he died August 10, aged 53, of arteriosclerotic heart disease.

Irvin Immanuel Pogue, Scott, Miss.; University of Tennessee College of Medicine, Memphis, 1916; member of the American Medical Association; died August 26, aged 57, of leukemia.

Clark Crandall Post, Barron, Wis.; College of Physicians and Surgeons of Chicago, 1893; served during World War I; died August 4, aged 81, of cerebral hemorrhage.

William Porter Pratt, Quincy, Mass.; Tufts College Medical School, Boston, 1907; member of the American Medical Association; on the staff of the Quincy City Hospital; died August 15, aged 71.

Alfred Pulford, Toledo, Ohio; Homeopathic Hospital College, Cleveland, 1885; died August 4, aged 85, of cerebral thrombosis.

Israel Kay Redd, Ellerson, Va.; Medical College of Virginia, Richmond, 1914; member of the American Medical Association; died in St. Luke's Hospital, Richmond, August 21, aged 55, of coronary artery disease.

Frances A. Ring, Chicago; Harvey Medical College, Chicago, 1903; member of the American Medical Association; served as examining physician at the Juvenile Court; died August 20, aged 86, of Buerger's disease and gangrene of the right foot.

Budd Robbins ⊕ Hanford, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; died August 17, aged 61.

Hector Morrison Ross, Chicago; University of Illinois College of Medicine, Chicago, 1926; member of the American Medical Association; affiliated with the Martha Washington Hospital; died August 27, aged 47, of coronary occlusion.

Hollace Rector Royster ⊕ Frankfort, Ind.; University of Illinois College of Medicine, Chicago, 1917; died August 6, aged 59.

Raymond Wentworth Runyan ⊕ Panama, Republic of Panama; Medical College of Ohio, Cincinnati, 1906; member of the Medical Association of the Isthmian Canal Zone; fellow of the American College of Surgeons; on the staff of the Hospital de Panama; died September 17, aged 63, of heart disease.

William Carl Schmidt ⊕ Augusta, Mo.; St. Louis College of Physicians and Surgeons, 1898; died in St. Joseph Hospital, St. Charles, August 9, aged 74.

Lester L. Scott, Siloam Springs, Ark.; University of Louisville (Ky.) Medical Department, 1907; member of the American Medical Association; died August 11, aged 65.

Levi Tillman Slayden, Tuckerman, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; Missouri Medical College, St. Louis, 1895; died August 23, aged 73.

Edward Byrnes Smith, Shelbyville, Ky.; Chicago Homeopathic Medical College, 1895; died August 5, aged 76, of angina pectoris.

James Walker Smith, Miami, Fla.; Northwestern University Medical School, Chicago, 1894; member of the American Medical Association; fellow of the American College of Surgeons; at one time practiced in Baguio and Manila in the Philippine Islands; died in Jackson Memorial Hospital August 14, aged 78, of bronchopneumonia.

Peder Soe ⊕ Kimballton, Iowa; Chicago Homeopathic Medical College, 1893; past president of the Audubon County Medical Society; served on the school board and town council; bank president; died in a hospital at Council Bluffs August 18, aged 86, of heart disease.

Alvin P. Stauffer, Hagerstown, Md.; Pulte Medical College, Homeopathic, Cincinnati, 1885; member of the American Medical Association; formerly member of the county board of education; died August 3, aged 91, of senility.

Thomas Turner Thomas ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1895; formerly on the faculty of his alma mater and of the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; fellow of the American College of Surgeons; an Affiliate Fellow of the American Medical Association; affiliated with Northeastern Hospital; died in Avon, N. J., August 7, aged 82, of arteriosclerosis.

James Handy Truitt, Glenn Dale, Md.; Chattanooga (Tenn.) Medical College, 1904; also a graduate in pharmacy; served during World War I; past president of the Prince Georges County Firemen's Association; formerly on the staff of the Casualty Hospital; died in the Mount Alto Hospital, Washington, D. C., August 8, aged 78, of heart disease.

Abraham Wallerstein, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1924; member of the American Medical Association; on the staff of the Beth Moses Hospital; died in Doctors Hospital August 8, aged 48, of carcinoma of the liver.

Wallace W. Wheat, Rosedale, Ind.; Eclectic Medical Institute, Cincinnati, 1899; died recently, aged 70.

Boyd Thompson Williams, Hudson, Wis.; Cincinnati College of Medicine and Surgery, 1901; died August 9, aged 71, of myocardial degeneration and purpura hemorrhagica.

First Human Case of "Black Disease of Sheep"

Mollaret and Guéniot have just reported to the Société Médicale des Hôpitaux de Paris observation of severe icterus in yellow atrophy of the liver due to an anerobic microbe, Clostridium oedematiens (Weinberg and Séguin 1915). A patient with general paralysis with positive Wassermann reaction (3 plus) in the blood and the special fluid was, after twenty-one days of observation, transferred in a generally good state to the ward of the authors for therapeutic malaria. Suddenly, the next day, he was seriously ill with a temperature of 39.5 C. (102.2 F.), subicterus at the level of the conjunctivas without hemorrhagic syndrome and a feeble pulse with a rate of 126. Abdominal examination did not reveal abnormality, but the dulness of the liver could hardly be outlined and there was oliguria with neither albuminuria nor glycosuria. The state of the patient became worse from hour to hour; the icterus increased in the afternoon, and the patient fell into a deep coma. He died during the night. Autopsy revealed the presence of Cl. oedematiens in a pure state, necrosis of hepatic cells, but the conservation of the architecture of the lobule and integrity of the vessels and of the bile duct. The kidneys presented necrosis of the epithelial cells. The good state of the pancreas and of the spleen and the conservation of the spermatozoa in the testicles prove that the aforementioned injuries were not due to the cadaveric autolysis, but to the toxin of the Cl. oedematiens. Hitherto this anerobe was only known as a cause of the peracute degenerative necrosing hepatitis of sheep, "the black disease." This first human case is worth being reported, as it adds a new causation for peracute severe primitive icterus. The authors emphasize that an immediate treatment with massive doses of specific antitoxin and penicillin might be effective in other possible cases.

Exchange Transfusions in Acute Leukemia

In the Paris letter of March 30, 1948, published in The Journal May 22, page 400, treatment of acute leukemia by means of exchange transfusions by Drs. Bessis and Bernard was reported. P. Croizat Révol and his collaborators reported to la Société Médicale des Hôpitaux de Lyon 5 cases of acute leukemia treated by the same method.

By repeated exchange transfusions (15 to 20 liters of injected blood), the authors obtained a noticeable lowering of the number of white blood cells, an increase in the number of red cells and a remarkable improvement in the medullary and blood formula in several cases, but this effect was only temporary (it lasted three months in 1 case). The patients died later, in spite of the repetition of the same treatment, combined sometimes with cautious radiotherapy.

Exchange Transfusions in Acute Azotemic Nephritis

Professor Pasteur-Valery-Radot, P. Milliez and their collaborators have just reported observation of a case of acute post abortum nephritis following septicemia due to Clostridium welchii.

Twenty-four hours after the beginning of this disease, one noted generalized icterus, extreme oliguria with hemoglobinuria, azotemia (2 Gm.) and anemia (1,600,000 red blood cells). Under the influence of penicillin therapy, immediately instituted, the septicemia disappeared. The second day of the disease, an exchange transfusion of 7 liters was made; this removed the effects of the icterus and did away with the anemia in a few hours, but the azotemic nephritis persisted. During sixteen days of oliguria, when the blood urea reached 4 Gm. per liter, the authors gave four exchange transfusions (totaling 21.35 liters). Suddenly, on the seventeenth day, diuresis was established without modification of the urea concentration of the urine, which stayed at 6 to 8 Gm. per thousand. The blood urea fell progressively to reach a normal rate on the twenty-fifth day. The author made a sixth exchange transfusion twenty-four hours after the reestablishment of diuresis. This treatment prevented the azotemia from increasing in spite of the extreme oliguria and permitted awaiting for restoration of diuresis. The authors insist on the harmlessness and ease of this method and on its advantages over peritoneal dialysis, intestinal perfusion and the artificial kidney, application of which is more difficult.

A. Tzank and J. Dausset have also used this treatment in 3 cases of anuria. In a case of scarlatinal nephritis with anuria, with blood urea at 3.25 Gm. per thousand, pulmonary edema and fall of arterial tension, an exchange transfusion gave a spectacular result: Diuresis was reestablished suddenly (3 liters) with a urea concentration at 15.11 Gm. per liter. Recovery was rapid and complete. Complete urinary tests showed that the renal balance was normal.

In a case of mercurial nephritis with extreme oliguria, the first exchange transfusion of 4.5 liters immediately improved the general state; next day diuresis was established. The urea concentration in the urine varied from 10.3 to 14.95 Gm., but the effect rapidly diminished in spite of repeated exchange transfusions (unfortunately in insufficient quantity). The patient died on the twenty-fifth day of her illness with toxic myocarditis. The amount of urine in twenty-four hours had reached 760.3 cc.; the blood urea was 5.5 Gm. per liter, and the urea in the urine 8.45 Gm. The autopsy showed big pale kidneys, without renal sclerosis, with lesions which were probably not irreversible.

In another case of mercurial nephritis with anuria, the authors gave eight exchange transfusions totaling 29.25 liters of blood, diluted one third. Diuresis was reestablished, blood urea was progressively reduced from 3.5 to 0.95 per liter, and urea concentration in the urine was increased.

The authors emphasize that the carrying out of the treatment must be based on the blood urea concentration. When an exchange-transfusion has lowered it from 2 to 3 Gm. one may reduce the quantity of blood the next time (never less than 4 liters per adult) and space the transfusions.

As to the action of this treatment, the authors think that new blood does not act by simple substitution, but that it provokes the indispensable metabolism not only at the level of the kidney but also of the liver and the entire organism.

Miscellaneous

The international review of medicine and therapeutics *Le Monde Médical* has just resumed publication.

The Third International Congress of Acupuncture will take place in Paris June 3-5, 1949. The general meeting of the International Union against Cancer which was to take place in Paris in 1948 has been postponed to 1949, on a date not yet selected.

Death of Professor Bezançon

Professor Fernand Bezançon, a member for thirty years of the Académie Nationale de Médecine, recently died at the age of 80 years. A bacteriologist schooled by Chantemesse and Vidal, he was at the same time a pathologist, physiologist and, above all, a clinician.

Several of his works are classics. He devoted himself to the study of tuberculosis and its social repercussions. He succeeded Letulle at the Hôpital Boucicaut; he pursued experiments in social politics. He succeeded Léon Bernard at the Clinique de de Laënnec, and became the great master of French phthisiology.

He was the leading member of the Société de la Tuberculose, of the Comité National de Défense contre la Tuberculose and of the Commission on Tuberculosis at the Ministry of Public Health until his last days.

Florence, Sept. 30, 1948.

Blood and the Digestive Apparatus

At the National Congress of the Italian Association of Gastroenterologists, held in Chianciano under the chairmanship of Prof. Gasbarrini from the Medical Clinic in Bologna, reports were presented on the subject "Blood and the Digestive Apparatus." The speakers were Professors Marmont from the University of Genoa, Meneghini from Genoa and Torrioli from Rome. Marmont stated that consideration of the general phenomena of the vegetative sphere may demonstrate the necessity of an intercellular fluid endowed with at least three properties: (1) the vehicle for the nutritive substances, (2) sufficient supply of oxygen, and (3) removal of the refuse of cells. A thorough analysis has not been made of the importance of the elementary factors which take part in hemoplasmopoiesis. This problem may be of interest to the clinician in those cases in which it is uncertain at what point in the pathogenesis of disease the dietetic deficiency factor sets in and when the digestive change begins which causes the hemopathy. For erythropoiesis, vitamins, amino acid and mineral factors are considered necessary. The speaker stressed the importance of ascorbic acid, para-aminobenzoic acid, riboflavin and the so-called blood factors of the vitamin B complex. Three metallic elements, iron, copper and cobalt, are important in erythrogenesis. The predominant part is played by iron, which may be observed in ionizable form in the food. A deficiency of copper in the diet is responsible for a neuroanemic syndrome in sheep, and in human infants there is a characteristic hypercupremia associated with hyposideremia in infectious anemia. A deficiency of cobalt is the cause of an enzootic marasmus of cattle, while in man the administration of this metal may cause polyglobulism under normal conditions and may restore to normal the impaired erythropoiesis in tumoral or infectious anemia. One may distinguish three fundamental types of gastroenterogenic anemias: hyperchromic macrocytic, hypochromic mycrocytic and normocytic. The gastroduodenal factors are of primary importance in the determinism of the hypochromic microcytic, iron-deficient anemias. The speaker discussed iron-deficient chloranemia in women. He considers the concept of selective absorption, which has been emphasized by some American authors, as an unsufficient explanation, and he suggests the possible intervention of diencephalic neurovegetative factors which will provide a new orientation concerning chlorosis.

Professor Meneghini discussed the pathogenesis of anemias which follow gastric resection. Pernicious anemia resulting from a deficiency of the intrinsic factor may follow total removal of the stomach. Partial resection of the stomach may be followed by manifestations of pernicious anemia, or of mycrocytic hypochromic anemia, or even anemia of normocytic aregenerative type, which usually is normochromic. This last form may have its pathogenesis in a deficiency of a third gastric factor which stimulates erythropoiesis; this concept seems warranted by the results of animal experiments. The polyglobulism observed in patients with gastroduodenal ulcers has been interpreted as of gastrogenic origin. In view of the importance of the diencephalic centers in the pathogenesis of gastroduodenal ulcers and the existence of diencephalic polyglobulism, nervous centers for the pathogenesis of hyperglobulism must be admitted, but they may be influenced indirectly by an increased gastrohormonal activity.

Torrioli reported a series of studies concerning the relation of the alimentary canal to hemopoiesis. The starting point for these studies was the concept that pernicious anemia may be a disease with symptoms of multiple deficiencies among which there may easily be recognized a deficiency of the antianemic principle, of iron and of vitamin B. The complex problem may be clarified, in part, by the study and the complete examination of a large number of families whose members are affected by pernicious anemia. This work had been in progress at the Center for Blood Diseases in Rome. The speaker reported the following results of a two year follow-up on 200 families: (*a*) Hypochromemia with reduced absolute values of circulating hemoglobin and associated with hyperglobulism in some cases, has been the most frequent observation among relatives of patients with pernicious anemia. Anemia occurred most frequently in these persons as a sequela of any minimum pathologic cause, such as adenopathy and influenza. (*b*) The erythrocytometric curve is profoundly altered with multiform changes which may be related to three fundamental types as follows: deviation to the left, deviation to the right, enlarged and lowered curve or diphasic or flattened curve. (*c*) Oral disorders occur such as atrophy of the lingual mucosa or changes in the paradentium (familial dystrophic paradentiopathy). (*d*) Oligochylia occurs; this alteration may be less frequent and may not be present necessarily in persons who may present the other changes in a most pronounced degree.

The problem concerning anisocytosis is much more complex. According to the majority of authors, the erythrocytic curve will be restored to normal in patients who have recovered definitely from pernicious anemia, and it should therefore be considered as linked with a deficiency of the antianemic prinicple. Starting from this concept, the speaker and his co-workers concluded that patients who recovered from pernicious anemia did not present a normal erythrocytometric curve, but showed the fundamental changes which were observed in their parentage, after the disappearance of the megalocytic generation. The authors also concluded that the ground on which pernicious anemia may develop is characterized by a syndrome of a gastrointestinal lability which is manifested by a hypofunction of all the mucosae. But besides of this debility one must consider a hematic abnormality which is manifested by decisive alterations of the red cells and with a constant deficiency of circulating hemoglobin; i. e., one which predisposes a person to easy anemization resulting from inadequate causes. The speaker does not believe that it may actually be possible to establish that all these abnormalities may be considered as congenital, or that on the contrary they may be related only to gastrointestinal lability. A solution for these important problems may be achieved during subsequent development of these investigations.

Treatment of Cardiac Insufficiency by Ligating the Vena Cava

In a previous letter on the work of Pedro Cossio and J. Perianes (The Journal June 12, 1948, p. 659), reference was made to their experiments for relieving congestion of the lungs due to insufficiency of the left ventricle or mitral stenosis. In continuing the experiments, these authors attempted to reach their goal in two ways: (1) by accelerating the release of stagnated blood in the lesser circulation by anastomosing a pulmonary vein or a branch of the arteria pulmonalis with an extrathoracic vein or (2) by decreasing the amount of blood which passes through the right ventricle. They hoped to obtain this purpose (1) through tricuspid valvotomy and (2) through diminution of the venous blood coming back to the heart. At the beginning of the experiments, the vena cava inferior was narrowed in different degrees above the outlet of the venae suprahepaticae, but with little success. Almost all the animals died because of thrombosis, intestinal infarcts or intrahepatic hemorrhages. It was difficult, indeed, to produce stenosis sufficient to diminish the pressure in the lesser circulation and at the same time not produce the aforementioned complications.

Ligation of the vena cava inferior above the suprahepaticae, reducing its lumen one-half, provokes an abrupt fall of the pressure in the right side of the heart and the arteria pulmonalis; on the other hand, ligation of the vena cava beneath the renales diminishes the pressure less, but more gradually, and does not provoke any functional disturbance.

As ligation of the vena cava has already been done for such other purposes as phlebothrombosis and thrombophlebitis after childbirth, it was decided to do it in cases of cardiac insufficiency which could not be controlled by medical treatment. The first attempt with local anesthesia in the zone of the incision failed because of violent pain provoked by detachment of the peritoneum. In 2 other cases general anesthesia with ether was used, but the operative accidents were so great that this method was abandoned, although the patients recovered and their cardiac condition was improved. Five more patients have been treated, all under local anesthesia, but this time combined with truncal anesthesia of the six or eight last intercostal roots and of the lumbar roots, and this with full success.

Before the operation, most of the patients were moribund. Two complications must be mentioned: phlebothrombosis and hypotension after the operation. Phlebothrombosis may be avoided by administering heparin or dicumarol for several days. The hypotension is more frequent. It is necessary to control the blood pressure during the whole operation and each hour afterward. It can be controlled by the Trendelenburg position and the usual analeptics. The results can be considered satisfactory. The dyspnea and the congestion diminish or disappear; the patient does not need to sleep sitting up; the venous pressure diminishes and does not rise when the lower extremities are elevated, and generally to further intensive medical treatment is not necessary.

However, the number of cases is yet too small for one to judge the value of this new procedure and to make definite interpretations.

Finally, the authors have ligated in animals all the great extrathoracic venous trunks with exception of the venae portae, affluentes and renales. The tolerance has been good. More cannot be said for the moment.

Sensitivity to Streptomycin

Drs. R. Cucchiani Acevedo and S. Erdstein reported to the Argentine Society of Tuberculosis observations among nurses who administer streptomycin to tuberculous patients. In 7 nurses, almost simultaneously, rosy and intensively pruriginous papules appeared on the fingers, sometimes preceded by erythema; later, vesicles developed with intense pruritus, swelling, perionyxis, vesiculation, fissures and desquamation. Later, the exanthem appeared with the same symptoms at the bend of the elbow; there was pruritus in both eyelids with sensation of drowsiness, periorbital edema, conjunctival congestion and photophobia. Similar phenomena have been observed in other institutions. The observations made by Rauchwerger and his co-workers (The Journal, Feb. 28, 1948) seem to be similar to those of the authors.

All the affected nurses had been in contact with the drug for many months, but the symptoms appeared only in the last eight weeks; it is therefore supposed that the hypersensitivity develops only after prolonged exposure to the drug. The localizations in the elbow and periorbital areas are explained by the fine nebulization which takes place when the injection is prepared by the nurses. Diphenhydramine hydrochloride ("benadryl hydrochloride") and "antistin" (2-[*N*-phenyl-*N*-benzyl-aminoethyl] imidazotin) did not give favorable results; however, autohemotherapy diminished the pruritus. Desensitization with 25 units of streptomycin intradermally produced pruriginous erythema with exacerbations when 50 units were injected.

As a prophylactic measure, some nurses prepare the solution and others inject it, using gloves and spectacles, avoiding the vapor by cooling the liquid before opening the bottle. Since then new cases have not been observed in the nurses. In 2 nurses not in contact with the drug for a month or so these manifestations disappeared completely but reappeared when they again were handling the drug.

The intradermal reaction should be carried out periodically with all the persons exposed to streptomycin, and a nurse should be temporarily withdrawn from the service when the first positive signs appear. It must be realized that patients treated with streptomycin might have such reactions when, after this medication has been stopped, the drug is readministered.

Number of Physicians in the Argentine

The National Direction of Investigations, Statistics and Census in Buenos Aires has published the results of a census of physicians and related professions in the Argentine in 1947. The sum total of practicing physicians is 18,301, 7,588 of whom practice in the capital, Buenos Aires, and 4,880 in the province of Buenos Aires. There are 6,643 dental surgeons. Seven hundred and twenty-five of the 3,548 midwives are in the capital, Buenos Aires.

Brief Items

Dr. Max A. Goldzieher, New York, gave several lectures in Buenos Aires, before the Argentine Medical Association, on the endocrine aspects of the arterial hypertension.

The Argentine Society for the Study of Sterility has been founded in Buenos Aires, similar to the societies already existing in other countries, under the chairmanship of Dr. Juan Carlos Ahumada, titular professor of gynecology. During the first session, in the Faculty of Medicine, Dr. John P. Greenhill (Chicago) addressed the audience on "Artificial Insemination."

The First Congress on Thoracic Surgery has been held in Buenos Aires under the chairmanship of the titular professor of this specialty, Dr. Jorge A. Taiana.

Mannitol-Indole-Negative Members of Genus Shigella

In a recent paper, Dr. B. Rangel Pestana, of the Adolpho Lutz Institute, the central laboratory of the São Paulo State Department of Health, reports his study of several strains of Shigella dysenteriae that, contrarily to what is stated in Bergey's textbook, do not ferment raffinose and adonitol. A comparative study of S. dysenteriae strains and other mannitol-indole-negative organisms isolated from clinical cases of dysentery and similar to S. dysenteriae in morphologic, staining, cultural and biochemical characteristics, although serologically different, revealed, for the first time, the occurrence in São Paulo of Shigella sp. Sachs Q771. The practical value is obvious, for if this type is regarded, as it was until recently in several countries, as inagglutinable Shigella, the use of Shigella antiserum which would be recommended as the specific treatment would be of no value. Sorbitol and l-arabinose are the means to differentiate S. dysenteriae from Sachs type Q771, but the differentiation is not possible by morphologic, staining and cultural characteristics or by routine biochemical tests. S. dysenteriae fails to ferment any of those carbohydrates, while culture of type Q771 produces, as a rule slowly, an acid reaction. However, the only representative strain of Shigella sp. Sachs Q1167 examined by Pestana, which was received from the Connecticut State Department of Health, presented the same biochemical behavior as did Shigella sp. Sachs Q771, although they are serologically distinct; this proves the necessity of typing by means of specific serums. Unless the contrary can be shown by future investigations, the S. dysenteriae strains repeatedly observed by the author as well as strains of type Q771, when compared with those of Wheeler and Stuart, permit the differentiation, by means of l-arabinose, of S. dysenteriae from the Sachs indole-negative types, as the latter produce acid from this carbohydrate, whereas the contrary occurs with S. dysenteriae. The distinction between these types is based on serologic tests.

The Sachs types will introduce modifications in the present taxonomic systems. Borman, Stuart and Wheeler, in a detailed study on the taxonomy of the family Enterobacteriaceae, to which the Shigella genus belongs, speak of the probable immediate necessity of designating varieties in the non-mannitol-fermenting group, but express the opinion that it is still too early to determine the exact place of germs recently described as of the Sachs type. However, the paper by Wheeler and Stuart excludes from the genus Shigella some Sachs types and confirms the inclusion of the remaining strains, in this manner defining their taxonomic positions.

On the basis of his experiments, Pestana insists on the necessity of the routine use of cultures and S antiserums in agglutination tests. Beside many of the so-called inagglutinable Shigella organisms reported, which are, in fact, not S. dysenteriae, but Sachs indole-negative types, a greater number exists which owe their inagglutinability to the use of R forms instead of S forms. He also states that both the S and R forms of S. dysenteriae are toxic. Under the same conditions, neither S nor R strains of Shigella sp. Sachs Q771 showed toxicity.

Peritesticular Reaction in Leishmaniasis of Guinea Pig

In his studies of spontaneous leishmaniasis of the guinea pig, Dr. C. Magarinos Torres, of the Division of Protozoology of the Oswaldo Cruz Institute, Rio de Janeiro, disclosed that male guinea pigs given injections of Leishmania enriettii (saline suspensions of cutaneous lesions from another infected guinea pig) in the peritoneum showed curious changes in the tunica vaginalis. As a result of such changes, induration of the epididymis as well as the formation of a definite juxtatesticular nodule was observed, but without any involvement of the testis and the epididymis themselves. The histologic picture is rather complicated. In the early stages it resembles in some aspects the Shwartzman phenomenon, while certainly not identical to it, as could be easily inferred by the entirely different factors at work in the 2 cases. Later on and gradually the leishmaniotic granuloma containing a large number of parasites (L. enriettii) appears, accompanied by hemorrhages, thrombosis and suppuration, which are so prominent in the early stages. Further research is needed in order to establish the exact mechanism of this peritesticular reaction. The possibility of another infectious disease at work has not so far received confirmation.

Report on Patients with Heart Disease

Dr. Reinaldo Chiaverini reported a study of 429 patients with heart disease attended at the Misericordia Hospital of São Paulo. The causes were, in decreasing order of frequency, arterial hypertension in 31 per cent of the cases, coronary arteriosclerosis in 22 per cent, cardiovascular rheumatism in 16 per cent, syphilis in 13 per cent, American trypanosomiasis (Chagas' disease) in 7 per cent, pulmonary hypertension in 3 per cent, and other causes in 8 per cent. In more than one third of the cases there were several causes in the same patient, the association of arterial hypertension and coronary sclerosis (17 per cent), and syphilis and arteriosclerosis hypertension (6 per cent) being the most common. Cardioarticular rheumatism and American trypanosomiasis were the most frequent independent causes of heart disease, while arterial hypertension and coronary sclerosis were the most frequently associated causes, together or with other disease. The principal cause of aortic insufficiency was syphilis (63.5 per cent of the cases), followed by rheumatism (33.8 per cent) and other causes (2.7 per cent). In 22 cases (or 5.1 per cent) a severe, chronic myocardial disease was diagnosed of undisclosed cause. In only 12 cases (2.7 per cent) myocardial infarct was the cause of the trouble, which seems to indicate that this disease is not frequent in the economically lower part of the city population which is served by the Misericordia Hospital. Congestive cardiac failure was present in almost 90 per cent of the patients, while the most frequent disturbances of rhythm and conduction were branch block (12 per cent), auricular fibrillation (12 per cent) and different degrees of auriculoventricular block (3 per cent). The disease presenting the greatest tendency to disturb the conduction system of the heart was American trypanosomiasis, which caused auriculoventricular block in 10 per cent of the patients and branch block in 40 per cent. Rheumatic and sclerotic diseases of the heart were the most common causes of auricular fibrillation, being present in 21.4 per cent and 17.8 per cent, respectively.

Esophageal Electrocardiogram in Posterior Infarction

In view of the difficulties often encountered in the electrocardiographic diagnosis of old posterior infarction, multiple esophageal leads were taken by Drs. Aarão Benchimol, Paulo Schlesinger and Murilo Cotrim of Hospital Moncorvo Filho, Rio de Janeiro, in 11 patients in whom the presence of infarction was suggested by the usual standards and unipolar extremity leads or by a positive clinical history. The configuration of the normal esophageal electrocardiogram was studied in 3 patients, with particular reference to the shape of the QRS complexes recorded at the auriculoventricular transition. A classification of posterior infarction is presented according to extension and depth of myocardial involvement as judged by esophageal leads.

Although posterior infarction can usually be recognized by standard leads and the unipolar lead of the left leg, there are certain cases in which esophageal leads are required for a positive diagnosis. Multiple leads at various esophageal levels should always be taken, since an incomplete exploration may occasionally fail to reveal the presence of localized lesions of the posterior wall of the left ventricle.

An Unusual Case of Endometriosis

A case of endometriosis in a uniparous white Brazilian woman, aged 43, is reported by Prof. Clovis Corrêa da Costa of the Faculdade de Ciencias Medicas of Río de Janeiro. The patient stated that since she was 25 she has noticed hard, painful nodules in the inner aspect of the thighs, which always got red before menstruation and finally bled. She also complained of dysmenorrhea. The nodules showed scarlike changes after menstruation, preceding new ones which appear soon afterward. About seven years ago similar formations appeared in the lower mammary grooves on both sides, on the pectoralis regions and neighborhood of the axillary plicae. Gynecologic examination showed retroflexed uterus with a small fibroid in its posterior aspect.

Reference is made by Prof. Corrêa da Costa to 2 other cases of external endometriosis, one on the internal aspect of the thigh and a similar case on the hand.

HEMORRHAGE FROM ESOPHAGEAL VARICES

To The Editor:—In the February 28 issue of The Journal, page 616, a paper entitled "The Hemorrhagic Tendency in Congestive Splenomegaly (Banti's Syndrome)" appears; this was first presented by Dr. L. M. Tocantins at the annual session of the American Medical Association, June 12, 1947. He referred to a case of hemorrhage from esophageal varices treated by tamponade at the Pennsylvania Hospital, Philadelphia, in May 1945.

Since this was apparently the first recorded instance of treatment by this method, I thought the enclosed photographs of roentgenograms of the patient taken with the balloon in place might be of interest. Associates and I used a Miller-Abbott tube and balloon. Pressure was maintained by connecting the balloon to a mercury sphygmomanometer. The tube was held in place by a tie placed around the head and secured at the nares.

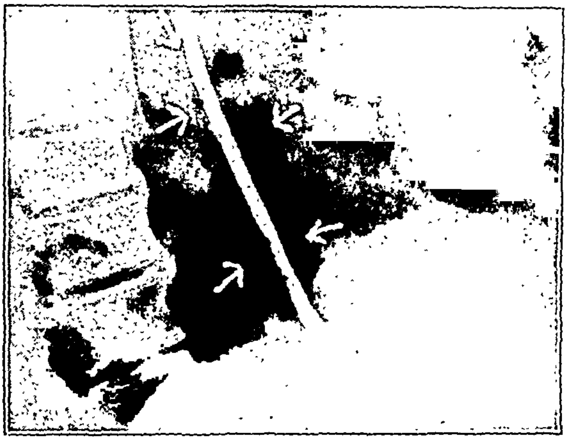

Fig. 1.—Oblique view of esophagus and cardia with balloon inflated.

This was one of several cases of bleeding esophageal varices so treated at that time. In this small series of cases, as an emergency life-saving measure, it was of definite value.

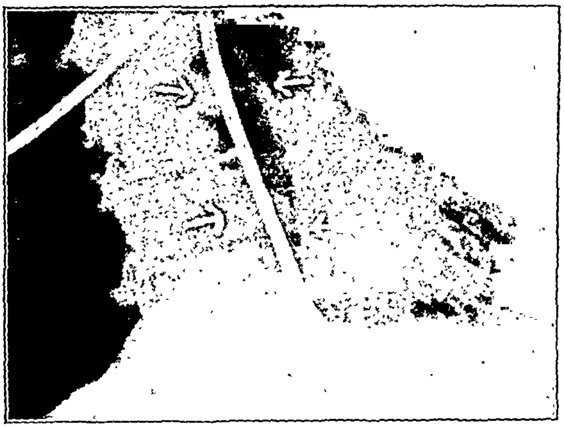

Fig. 2.—Lateral view of esophagus and cardia with the balloon inflated. The arrows indicate the air shadow of the inflated balloon in the lower end of the esophagus and cardiac end of the stomach.

The first patient was in extremis when treatment was instituted, and died six hours later. The second case was complicated by far advanced hemochromatosis, and the patient died two days following intubation. Both of these patients stopped bleeding, as evidenced by absence of blood on gastric suction. Both cases at post mortem showed evidence of esophageal varices and effective placement of the balloon. The third case is the one discussed by Dr. Tocantins. A fourth case, in a woman of 35 years, was diagnosed as Banti's syndrome complicated by bleeding esophageal varices. Her response was as dramatic as that in the third case. She left the hospital ten days after admission, asymptomatic.

Since returning from the service, we are at present enlarging our small series. Dr. Tocantin's modifications have been proving effective. In one case, a three lumen tube was passed so that tube feeding could be used while the balloon was in place. We hope to present this material as the subject of a report in the near future.

Edward W. Bixby Jr., M.D.,
Pennsylvania Hospital, Philadelphia.

CHLOROMYCETIN

To the Editor:—As you know, the October 9 issue of The Journal has an editorial on chloromycetin on page 432. The editorial states that "similar therapeutic effects were recorded with embryonated eggs infected with psittacosis virus, variola virus or influenza A virus." It further states that "chloromycetin was equally effective with mice infected with Japanese encephalitis." Both of these statements are incorrect. In their original paper Smadel and Jackson (*Science* **106**:418 [Oct. 31] 1947) stated that "chloromycetin has been ineffective in the treatment of mice infected with Japanese encephalitis and eggs infected with variola virus and influenza A virus. In another reference not quoted in the editorial (Smith and others, *J. Bact.* **55**:425 [March] 1948) chloromycetin was found to afford no protection against type A influenza, St. Louis encephalitis and fixed rabies virus infections in mice or in eggs.

I feel that it is important to call your attention to the errors in this editorial in order to avoid arousing false hopes on the value of chloromycetin in therapy of the virus diseases.

Albert Milzer, Ph.D.,
Michael Reese Hospital,
Chicago.

AUGUST WAS BAD MONTH FOR HORMONE CREAM PROMOTER

On Aug. 4, 1948, Daniel Platt pleaded guilty to a criminal information containing twelve counts, each of which represented an alleged violation of the Food, Drug and Cosmetic Act of 1938, based on representations made by the defendant in the promotion of a so-called bust-developing cream which he called "Formalon." A federal judge thereupon sentenced him to prison for a total of three years on the twelve counts, but suspended the sentence. A fine of $250 was then assessed on each of the twelve counts, or a total of $3,000. In addition, the court ordered the defendant Platt to be placed on probation for a period of three years, there being included a condition that he remove himself completely from any business relating directly or indirectly to the manufacture and sale of any drug or food product.

More recently Platt has been promoting another hormone cream breast-developer. This one he called "Manogin." A circular put out by the Manogin Company in the promotion of this product was so bad that it was felt necessary to comment on it in The Journal under the auspices of the Council on Pharmacy and Chemistry.[1]

The Post Office Department now announces that it has invoked a fraud order against the Manogin Company and its officers and agents as such. Aug. 20, 1948, was the effective date of such fraud order. The findings of fact on which the fraud order was issued brought out by way of expert testimony the uselessness of this preparation because of the small estrogenic content, even though used over long periods of time.

---

Council on Medical Education and Hospitals

Approval of the Chicago Medical School

The Chicago Medical School, located at 710 South Wolcott Avenue, was inspected by representatives of the Council on Medical Education and Hospitals and the Association of American Medical Colleges in October 1948. This inspection revealed that the Chicago Medical School offers an educational program that meets the Council's standards for an approved medical school. Accordingly, at its meeting on Nov. 9, 1948, the Council voted to admit the Chicago Medical School to its list of approved medical schools. By this action all students in regular attendance at the school on graduation will be considered by the Council to be graduates of an approved medical school. This action does not apply to students who completed their formal academic education at the school prior to Nov. 9, 1948 and who are now serving the year of internship required by the school before the degree of Doctor of Medicine is awarded. Likewise, this action does not affect the status of physicians who graduated from the school prior to Nov. 9, 1948.

On the same day that the Council voted to admit the Chicago Medical School to its approved list, the school was elected to membership in the Association of American Medical Colleges.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I & II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April, 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa.

EXAMINING BOARDS IN SPECIALTIES

American Board of Internal Medicine: *Oral.* San Francisco, Feb. 8-10, 1949. Final date for filing application is Dec. 1, 1948. New York City, March 23-25. Final date for filing application is Jan. 2. Philadelphia, June 1-3. Final date for filing application is Jan. 2. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Ophthalmology: *Written.* Jan. 14. *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: *Part I.* Various Centers, April & May. Final date for filing application is Dec. 31. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: St. Louis, Feb. 18-20. Baltimore, April 22-24. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine: Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, Georgia Warm Springs Foundation, Warm Springs, Ga.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Psychiatry & Neurology: *Oral.* May. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March 1949. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman 225 S. 15th St., Philadelphia.

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30, 1949. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska:* Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

California: *Oral.* Los Angeles, Nov. 20-21. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

Colorado:* Denver, Jan. 4-7. Final date for filing application is Dec. 18. Sec.-Treas., Dr. W. W. King, 831 Republic Bldg., Denver 2.

Delaware: *Examination.* Dover, Jan. 11-13. *Endorsement.* Jan. 20. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

Florida:* *Examination.* Jacksonville, Nov. 28-30. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

Hawaii: *Examination.* Honolulu, Jan. 10-13. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

Idaho: Boise, Jan. 10-12. Dir., Bureau of Occupational Licenses, Miss Estella S. Mulliner, State House, Boise.

Indiana: *Examination.* Indianapolis, June 1949. Sec., Board of Medical Registration & Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

Iowa:* *Examination.* Des Moines, Dec. 6-8. *Endorsement.* Des Moines, Dec. 6. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 15-16. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 13-15. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

Louisiana: *Examination.* New Orleans, Dec. Sec.-Treas., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans 12. *Homeopathic Examination.* Baton Rouge, subject to call. Sec., Dr. F. H. Hardenstein, 715 Pere Marquette Bldg., New Orleans.

Maryland: *Examination.* Baltimore, Dec. 14-17. *Endorsement.* At the discretion of the Board. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, Dec. 7-8. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Mississippi: *Reciprocity.* Jackson, Dec. 6. Exec. Officer, State Board of Health, Dr. Felix J. Underwood, Jackson.

Nebraska:* *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

New Hampshire: Concord, March 10. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New York: *Examination.* Various Centers, Feb. 1-4. Sec., Dr. J. L. Lochner, Jr., 23 S. Pearl St., Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, Jan. 17. Sec., Dr. Ivan M. Procter, 226 Hillsboro St., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 4-7. Act. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, Dec. 13-15. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oregon:* *Examination.* Jan. 5-7. Final date for filing application is Dec. 22, 1948. *Endorsement.* Jan. 21-22. Final date for filing application is Jan. 3. Exec. Sec., Mr. Howard I. Bobbitt, 608 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia, Jan., 1949. Act. Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: *Examination.* Santurce, March 1. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: *Endorsement.* Columbia, Dec. 6. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* Pierre, Jan. 18-19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

Utah: *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Vermont: *Examination.* Burlington, Feb. Sec., Dr. F. J. Lawliss, Richford.

Virgin Islands: *Examination.* Charlotte Amalie, Dec. 8-9. Comm., Dr. Christian R. Moorhead, Charlotte Amalie.

Virginia: *Examination.* Richmond, Dec. 3-4. *Endorsement.* Dec. 2. Sec., Dr. K. D. Graves, 30½ Franklin Road, Roanoke.

Washington:* Seattle, Jan. Sec., Dept. of Licenses, Miss Virginia Wotherspoon, Olympia.

West Virginia: Charleston, Jan. 3-5. Sec., Public Health Council, Dr. N. H. Dyer, Capitol Bldg., Charleston 5.

Wisconsin:* Madison, Jan. 11-13, 1949. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls, Wis.

Wyoming: *Examination.* Cheyenne, Feb. 7. Sec., Dr. Franklin D. Yoder, Cheyenne.

Minnesota: *Examination.* Jan. 4-5, April, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Oklahoma: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination.* Portland, Dec. Sec., Basic Science Examining Committee, Dr. C. D. Byrne, Univ. of Oregon, Eugene.

SOUTH DAKOTA. *Examination.* Vermillion, Dec. 3-4. Sec., Dr. G. M. Evans, Yankton.

TENNESSEE: *Examination.* Memphis, Dec. 30-31. Sec., Dr. O. W. Hyman, 874 Union Avenue, Memphis 3.

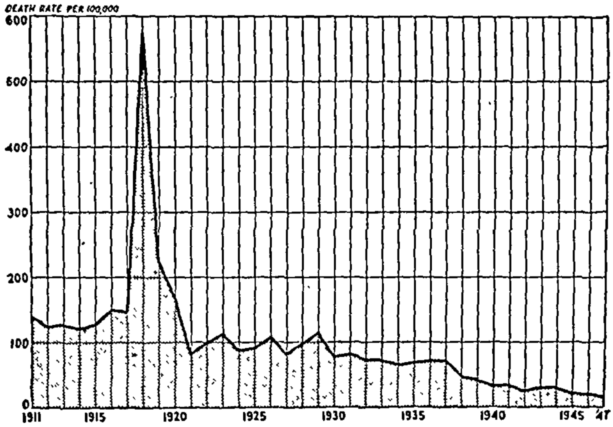
WASHINGTON: Seattle, Jan. Sec., Dept. of Licenses, Miss Virginia Wotherspoon, Olympia.

WISCONSIN: *Examination.* Milwaukee, Dec. 4. Final date for filing application is Nov. 27. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Miscellany

INFLUENZA AND PNEUMONIA—THIRTY YEARS AFTER THE PANDEMIC

Thirty years ago a worldwide epidemic of influenza struck the Atlantic seaboard and swept through the country in a general westerly direction along the main lines of transportation. It is estimated that about 20,000,000 persons in the United States were attacked, of whom 550,000 died. The explosive character of the outbreak is apparent from the chart, based on experience among the industrial policyholders of the Metropolitan Life Insurance Company. In 1918 the adjusted death rate from influenza and pneumonia among these insured (ages 1 to 74 years) was 575 per 100,000, or more than four times the average for the preceding seven years. During the last three months of the year, when the pandemic was at its height, the death rate from these diseases, on an annual basis, was more than eleven times the rate for the preceding twelve month period.



Mortality from pneumonia and influenza, 1911 to 1947; Metropolitan Life Insurance Company, weekly premium-paying business, ages 1 to 74. Annual death rates have been adjusted for changes in age, sex and color composition of these policy holders.

In the years since the pandemic, however, phenomenal progress has been made in reducing the mortality from influenza and pneumonia. A new era was inaugurated in the early thirties, when specific serum treatment for many types of pneumonia was introduced. The death rate among these policy holders dropped from about 80 per 100,000 in 1930-1931 to about 70 per 100,000 in 1936-1937, during which period this type of therapy came increasingly into use. But just as the serum treatment was proving its worth in the battle against pneumonia, treatment with the sulfonamide drugs was introduced. In 1938, when both serum and the sulfonamide drugs were used, the death rate from pneumonia and influenza dropped sharply to 46.9 per 100,000 policy holders, a decrease of almost 35 per cent from the year before. The continued improvement in treatment with sulfonamide drugs and the introduction of penicillin brougnt still further success. By 1947 the rate reached the all-time low of 17.4 per 100,000; the rate for the current year will probably fall still lower. The efficacy of the newer methods of treatment is clearly evident from the fact that the improvement in mortality has been relatively three times as great in the past decade as in the preceding one.—*Statistical Bulletin,* Metropolitan Life Insurance Company, September 1948.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Pharmacists: Sale of Barbiturate Capsules Without Prescription; Liability for Suicide of Purchaser.—The plaintiff sued for damages for the death of her husband alleged to have been caused by the wrongful act of the defendant pharmacist. From a judgment in favor of the defendant the plaintiff appealed to the Supreme Court of South Carolina.

Section 5128-25 of the South Carolina statutes, which the defendant is charged with having violated, provides that any person, firm or corporation selling any of that general class of synthetic drugs, commonly known as barbiturates or their counterparts, except on the written prescription of a licensed physician, shall be deemed guilty of a misdemeanor. The plaintiff alleged that her husband, after having suffered from a cold and influenza, went to the defendant's pharmacy and asked for some drug which would "ease his nervousness and promote sleep." In response to this request the defendant sold him some barbiturate capsules in a box or container without any label showing the contents thereof and without first receiving a physician's prescription directing such sale. Thereafter, over a period of about a year, the defendant, at the request of the deceased, continued to sell him these capsules. The plaintiff then alleged that the barbiturate preparation in question was a habit-forming drug, that the deceased was not advised of its nature and that as a result of taking the capsules he became habituated to the use of the drug, in consequence of which he deteriorated mentally and physically. While under the influence of the drug, or while suffering from moroseness, caused by its habitual use, the deceased committed suicide by hanging. The plaintiff then concluded with the allegation that the capsules were sold to her husband in violation of the law and that his death by suicide was the proximate result of the wrongful acts of the defendant pharmacist in making such sales.

South Carolina law authorizes the representative of an estate to sue for damages for the wrongful death of a person if the wrongful act which caused such death would have entitled the deceased to maintain an action and recover damages in respect thereof during his lifetime. The defendant contended that the drug habit of the deceased was a direct consequence of his own voluntary act in taking the barbiturate capsules and not the result of the sale of the drug to him; that the consumption of the capsules was an act independent of and entirely distinct from the sale, depending entirely on the free will of the purchaser, and that the consumption and not the sale was the proximate cause of any resulting injury; that the deceased, by the exercise of ordinary care, might have escaped making himself a drug addict and by not doing so, he was the author of his own act. It was therefore urged that no cause of action accrued under the statute.

The court pointed out that the complaint set forth that the deceased, from time to time during a period of about a year, bought barbiturate capsules from the defendant and that at the end of said time he committed suicide by hanging himself. It is nowhere specifically alleged, said the court, that the deceased was incapable of consenting to any one or more of the sales of capsules or that the defendant had any knowledge that he was incapable or lacked volition in making such purchases. There is nothing to show that the deceased lacked self control or judgment or that he appeared to be under the influence of any drug when he applied for the capsules. We think, concluded the Supreme Court, that the inference is inescapable that the deceased knew the nature of the drug. He certainly must have known it after taking the capsules following his first purchase. He continued to make periodic purchases and the complaint alleges that he acquired the drug habit. But long before he became an addict he must have realized the effect the drug was having on him and if he had survived and brought this suit, he would not have been heard to say that he was not taking a "narcotic." His own contributory negligence would bar the action.

The defendant next argued that he could not be held liable on the theory of proximate cause. In every case of this character, the Supreme Court pointed out, the inquiry is: Was the injury a natural and probable consequence of the wrongful act, and ought it to have been foreseen in the light of the attendant circumstances? In this case, the court continued, the deceased took his own life by hanging. Can it be reasonably said that his tragic end was a natural and probable consequence of the sale to him of the barbiturate capsules, and should it have been foreseen in the normal course of events? It might be that defendant should reasonably have foreseen that the deceased would become a drug addict but not that the deceased would kill himself. All that can be said is that the deceased's unlawful act could have produced a condition of mind out of which the tragedy could have resulted. However, so many elements may enter into a suicide that it is impossible to say that it was the natural and probable consequence of the negligence. In order to reach such a conclusion, continued the Supreme Court, we would have to eliminate entirely all those elements of feeling, temperament, disposition, emotional disorders, background and lack of self control, which might of themselves have been sufficient to bring about the tragic result, even though the person committing suicide had not been under the influence of a drug. While it may be true that some suicides may result from the excessive use of drugs, such as barbiturates, yet, as a vast majority of the persons who use this form of drug do not commit suicide, it could not be said that he who sells the drug may reasonably contemplate that suicide will follow. The voluntary wilful act of suicide of an uninjured person, who knows the purpose and physical effect of his act, is generally held to be such a new and independent agency as does not come within and complete a line of causation from the injury to the death so as to render the one responsible for the injury civilly liable for death. We think, the Supreme Court concluded, it would be going entirely too far in this case to hold that the unlawful sale of the barbiturate capsules brought about a condition of suicidal mania as the natural and probable consequences of the sale, or that this result should have been reasonably foreseen by the defendant. Accordingly the judgment of the trial court holding that the defendant pharmacist was not liable for the death of the plaintiff's husband, was affirmed. *Scott v. Greenville Pharmacy, Inc., 48 S. E. (2d) 324 (S. C., 1948).*

Workmen's Compensation Acts: Employee's Refusal to Cooperate with Physician.—The claimant commenced a proceeding to obtain an award under the workmen's compensation act for compensation for the loss of his leg. From a ruling against him by the Industrial Commission, the claimant appealed to the Supreme Court of Appeals of Virginia.

The claimant sustained an injury to his shin at the site of an old fracture and reported to the company physician on Sept. 16, 1946. The physician removed some necrotic tissue, applied an elastic bandage and told the claimant to return for further attention in two days. When he did not return as directed, Dr. Healy, the physician, went to the tool room where the claimant worked and tried to explain to him how serious the trouble was, because of the fact that the ulcer was superimposed on an old area of discolored skin caused by the previous fracture. The claimant was very indefinite and would not promise to come back. He did return, however, on October 18, at which time his leg was about in the same condition—still with an infected abrasion. He was again instructed to come back in two days, which he did. At that time the bandage applied by the doctor two days before had been removed and there was a badly soiled piece of cloth and some sort of grease on the wound, which the doctor cleaned off with ninol and ether. The claimant was again instructed to return two days later, but the doctor did not see him again until December 5, about six weeks later. At that time his leg was a little worse and the doctor again sought to impress on him the importance of having it attended to. In turn, the claimant tried to impress on the doctor how well he himself had been able to take care of other ulcers he had had on his legs, stating that he had had a similar accident in May and had cured it himself. He did not return to Dr. Healy for treatment after December 5. The leg was finally amputated by another physician about four months later.

Dr. Healy testified that he made every effort to induce the claimant to come to see him regularly but the claimant failed to do so. In addition to Dr. Healy's efforts, the shop foreman, at the request of the nurse in charge, told the claimant to go to the first aid room, but got no definite promise from him. Dr. Healy and the nurse called the claimant's immediate boss to see whether he could get him to come for treatment. The boss saw the claimant several times and told him to go. He testified that the claimant went some place, but whether he went to the first aid room he did not know. Torbert, a machinist, who was safety marshal and worked right at the tool room and who was a friend of the claimant, testified that on different occasions he was asked by the nurse, as a favor to her and to the claimant, to request the claimant to report for treatment. He did so, but the claimant did not go. He saw the claimant five different times. He and his father, who was a wholesale druggist, talked to the claimant several times about his leg. It seemed to be healing from the top, and the claimant was pulling the skin up from time to time to try to get healing from the bottom first. He asked Torbert whether he could get him a mixture of mutton tallow and turpentine. Torbert said that the claimant was trying to get cured all by himself and told Torbert he was not going to see the doctor and the nurse any more, as he could do more for his leg than they could.

The claimant did not contradict any of this evidence. His testimony was that he went to the first aid room as much as he could, which was eight or ten times, and that the reason he did not go oftener was because, as he expressed it, his job was at stake. On the other hand, there was evidence that permission to go for treatment could have been had at any time just for the asking. Furthermore, his immediate superiors, the doctor and the nurse, as well as his friend and co-worker, repeatedly urged him to go for treatment. The claimant did not testify that he ever made a specific request to go for treatment which was refused. Finally, Dr. Healy testified that if the claimant had come to him and taken treatments regularly he felt positive that his trouble would have been cured and that no amputation would have been necessary. There was no evidence of any kind to the contrary.

The Virginia workmen's compensation act provides that for a period not exceeding sixty days after an accident the employer shall furnish, free of charge, to the injured employee, such necessary medical attention as the nature of the accident may require, and the employee shall accept it, and during the remainder of disability, the employer may furnish, free of charge, an attending physician whom the employee shall accept, with certain exceptions and additions not involved in the present case. The law then goes on to provide, "The refusal of the employee to accept such service when provided by the employer shall bar said employee from further compensation until such refusal ceases, and no compensation shall at any time be paid for the period of suspension unless, in the opinion of the industrial commission, the circumstances justified the refusal, in which case the industrial commission may order a change in the medical or hospital service."

The questions presented by this appeal, said the Supreme Court of Appeals, are whether the employer furnished adequate medical services and attention and whether the claimant refused to accept them to such an extent as to bar him from compensation. On the basis of the evidence herein reviewed, the court was of the opinion that the claimant refused the medical attention offered him and urged on him, without any excuse for doing so other than his notion that he could take care of himself. This was not a legal excuse, said the court. The duty of the employee to accept such necessary medical attention as the nature of the accident may require is made compulsory by the statute. His refusal to do so, by like mandate of the statute, bars him from compensation until such refusal ceases. To have that consequence his refusal must be unreasonable and without just cause. The Industrial Commission found that "the preponderance of the evidence shows that all the complications which led to the amputation were due to his lack of cooperation and inexcusable refusal to receive the medical attention tendered him." This finding, concluded the Supreme Court of Appeals, is amply supported by the evidence. Accordingly the judgment of the Industrial Commission was affirmed and the employee was denied any compensation because of his failure to cooperate with the attending physician. *Stump v. Norfolk Shipbuilding & Dry Dock Corporation, 48 S. E. (2d) 209 (Va., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Simple Method of Determining Abnormalities of Q-T Interval. E. Goldberger.—p. 141.

Division of Atrioventricular Canal.—Rogers and Edwards report 5 cases of congenital cardiac disease termed incomplete division of the atrioventricular canal with patent interatrial foramen primum (persistent common atrioventricular ostium) and review the pathologic and clinical features in an additional 50 cases reported in the literature. In the entire group of 55 cases, the median age of the patients at the time of death was 10 months. More than half of the patients died before they were 1 year of age. Only 5 of the patients lived beyond the age of 30 years. The lesion under consideration acts essentially as does a simple interatrial septal defect. Enlargement of the right side of the heart and widening of pulmonary artery orifice are common secondary lesions. Cyanosis may be present at birth, but is usually acquired. When this manifestation develops, it is a sign of failure of the right side of the heart, pulmonary disease, or both. Cardiac murmurs, usually systolic, are frequently observed. Mongolism is a relatively common associated finding.

Rheumatic Infection in Childhood.—At the Children's Hospital of Philadelphia a register has been kept of all patients treated for rheumatic infection since 1922. In 1946 and 1947, a survey was made of all patients whose primary manifestation had occurred during the years 1923 to 1937, inclusive. Although many had been followed for much longer periods, the discussion is limited to the first ten years following the initial illness. At the termination of the initial attack 59.2 per cent of 547 children who were followed for ten years showed evidence of rheumatic heart disease. Of 219 patients with no clinical evidence of heart disease at termination of their first attack, 76.7 per cent still showed no evidence of heart disease ten years after onset. Only 5 per cent of this group with potential heart disease at onset had died of rheumatic infection or bacterial endocarditis. Of 318 patients with rheumatic heart disease at onset, 30 (9.4 per cent) showed disappearance of signs of cardiac involvement. Of this group with rheumatic heart disease at onset, 42.1 per cent had died of rheumatic infection or bacterial endocarditis. The most significant prognostic factor, so far as the initial illness is concerned, is related to the presence or absence of signs of cardiac damage. Chorea at onset is relatively benign, because it is less likely to be associated with carditis than is polyarthritis or other types of rheumatic infection. Ten years after onset, 60.3 per cent of these rheumatic patients were leading a normal existence. Those without clinical evidence of heart disease at the termination of the initial attack accounted for the majority of those presenting no functional incapacity. Twenty-four and four-tenths per cent of the total group had died of rheumatic infection, the predominant number of deaths occurring among those in whom a diagnosis of rheumatic heart disease had been made after recovery from the first attack. Death had occurred in only 5 per cent of the group in whom an original diagnosis of potential heart disease had been made, in comparison with a death rate of 42 per cent among those given a diagnosis of rheumatic heart disease at onset.

*Massive Gastric Hemorrhage in Pregnancy. J. Carangelo and T. D. Efstation.—p. 191.

Acute Anterior Poliomyelitis in Pregnancy.—*Taylor and Simmons* found that during the 1946 epidemic of poliomyelitis in Colorado the pregnant woman was twice as vulnerable to the virus disease as the nonpregnant woman of the same age group. Women in all months of pregnancy were equally susceptible to poliomyelitis. During the first two trimesters the prognosis for recovery is excellent. Poliomyelitis acquired during the last trimester carries a serious prognosis with respect to survival of the mother or escape from severe permanent paralysis. Estrogen and progesterone may be protective to a victim of poliomyelitis early in pregnancy. This is not true in the last trimester. The virus does not pass the placental barrier. All children born of mothers infected during this epidemic have been free from congenital disease. Management of pregnancy accompanied by acute poliomyelitis in the last trimester of pregnancy is a challenging problem. In the acutely ill patients, cesarean section seems unreasonable. Poliomyelitis had no ill effects on the progress of labor except that it necessitated an occasional forceps operation.

Massive Gastric Hemorrhage in Pregnancy.—*Carangelo* and his associates present the histories of 4 women who present the unusual complication of massive hemorrhage during pregnancy at term. Three presented an eclamptic syndrome of hypertension, edema, convulsions, oliguria and albuminuria. All 4 had severe projectile vomiting of blood, followed by marked decrease of blood pressure. In all, the onset of labor occurred twenty-four to twenty-eight hours following the onset of projectile hematemesis. Three of the patients were delivered of stillborn infants in whom the heart tones were not audible, following the onset of hematemesis. In 1 case, in which the mother survived, the infant was premature and viable. Pathologic study of case 1 revealed no specific source of hemorrhage in the esophagus or stomach in the form of varices. Superficial ulceration of the mucosa of the stomach and esophagus was noted. This may have been a source of bleeding, but it was not thought that it would have produced the amount of hematemesis noted clinically. The elevated temperature was probably due to the severe chronic endometritis in which there were necrosis and masses of bacteria in the endometrium. Together with this infection she had acute pyelonephritis bilaterally and an acute splenic tumor. This infection may have been the underlying cause of her massive hematemesis and the death of the fetus.

Nystagmus Induced by "Amytal" in Chronic Alcoholism.—While studying the effect of barbiturates on eye movements Bender and Brown observed that in chronic alcoholic addicts intravenous injection of "amytal sodium" (sodium isoamylethylbarbiturate) produced fine, shimmering nystagmus instead of the coarse and slow nystagmoid movement which is generally seen in barbiturate intoxication of persons not addicted to alcohol. Comparative tests were made on 15 alcoholic addicts and 15 controls not addicted to alcohol. A 5 per cent solution of "amytal sodium" was injected into the antecubital vein at a rate not exceeding 0.1 Gm. or 2 cc. per minute. The total dose was never more than 0.5 Gm. or 10 cc. During these tests the patients were instructed to fix their gaze on an object away from the central visual axis. In the control subjects injection of "amytal sodium" generally produced ocular responses of two types: (1) wide, slow irregular oscillations in which the eye drifted slowly toward the midline from a point of fixation and returned to the original position with a flick, and (2) coarse, slow rhythmic nystagmus. All patients addicted to alcohol showed fine shimmering nystagmus. In 1 patient the type of nystagmus helped the discovery that the patient had been an alcoholic addict, which he had denied at first. It appears that if alcohol is imbibed over a long period, it alters the function of the nervous system. The fine rapid nystagmus is found even months after the patient has stopped drinking. This suggests that alcohol produces a more or less permanent change in nervous system function.

Streptomycin Toxicity.—Davis and his co-workers report 117 patients who received streptomycin for some form of tuberculosis at the thoracic diseases service of the Birmingham Veterans Administration Hospital from January 1947 to January 1948. Streptomycin is considered sufficiently toxic to warrant recommending that it be administered only during hospitalization. Neurotoxic, anaphylactic, renal and general toxic reactions have been noted. Treatment was abandoned in 12 of the 117 patients because of severe toxic reaction after twelve to one hundred and five days of therapy. Of 105 patients who received 2 Gm. streptomycin for sixty to one hundred and twenty days 97 per cent manifested damage in the vestibular portion of the eighth cranial nerve, in which the neurotoxic selection by streptomycin is noted especially. In general, the onset of damage to the vestibular apparatus depends on the total amount of streptomycin received. Toxic effects on the cochlear portion of the eighth cranial nerve were relatively minor. Loss of hearing, chiefly in the high audiometric range, occurred in only 25 per cent of the patients. Loss of hearing in the audible range was noted in less than 3 per cent of the patients. More than 4 per cent eosinophils were noted in 78 of the 117 patients. In 18 correlation between good results of therapy and a high eosinophilia was noted, but 15 patients also obtained good results without eosinophilia, and in 8 patients with high eosinophilia poor results were observed. Leukopenia developed in 2 patients at the end of the sixty day regimen of treatment. A definite relation exists between the severity of toxic reactions and high levels of streptomycin in the blood.

Recurrence of Lupus After Skin Grafting.—Robinson and Tasker present the case of a woman, aged 50, who had had a lupus vulgaris lesion on the right cheek; the lesion had been excised and the area covered by a free thick skin graft. Although at first an excellent cosmetic result was obtained, about a year later there were signs of recurrence of the disease in the skin graft and scar. A review of the medical literature shows that despite the favorable reports from European investigators, frequent postoperative recurrences of the disease are observed in the United States. Since lupus vulgaris is frequently hematogenous in origin, the authors advise that if local surgical treatment is employed it should be combined with treatment for systemic tuberculosis.

Topical Application of Diphenhydramine.—According to McGavack and his associates diphenhydramine hydrochloride ("benadryl") has a powerful antihistaminic effect. The frequency of the side effects of the drug when given in adequate amounts by mouth has led to the investigation of its topical use for diseases in which cutaneous manifestations of a probably allergic nature are present. Topical application of 2 and 5 per cent concentrations of diphenhydramine in ointment bases in 63 patients reduced or completely destroyed the response of the skin to intradermally applied histamine. "Carbowax 1500" monostearate, an oil in water emulsion, appeared to be the best of the three bases employed. Seventy-four patients with itching dermatoses were treated with ointments containing diphenhydramine. Forty-four obtained complete relief from the itching, while an additional 18 were improved. Six patients experienced some discomfort from the application of the ointment, particularly when a 5 per cent concentration was used. In 4 of these patients this lasted not more than five minutes. Of the other 2, it was due to the base employed in one and to an aggravation of a weeping eczematous disease in the other. No systemic side reactions were observed in any of the 137 patients who were subjects of this study.

Cardiovascular Diseases: Review of Significant Publications from January 1944 to June 1947. O. Paul, with the editorial assistance of E. F. Bland and P. D. White.—p. 209.

Thrombosis and Internal Diseases.—Kallner emphasizes that in patients with pneumonia the temperature sometimes does not return to normal but remains subfebrile. The possibility of thrombosis must be considered. The appearance of blood-streaked sputum in these cases is probably a sign of pulmonary embolism pointing to the existence of thrombosis. In 3 such cases anticoagulant therapy with heparin and "dicumarol" produced rapid recovery. Heparin has been used in an instance of anuria caused by a hemolytic reaction after blood transfusion. Two hours after heparin was given the anuria cleared up. Heparin has also been successfully used together with ephedrine in cases of fibrinous bronchitis.

Hypoprothrombinemia: Administration of Vitamin K to Blood Donors.—This study by Butt and his associates was undertaken to repeat Kinsey's observation in cases of severe hepatitis with hemorrhagic manifestations which could not be controlled by administration of vitamin K or transfusion of whole blood. In attempting to control the hemorrhage, Kinsey administered 18 mg. of vitamin K intramuscularly to donors twenty-four hours prior to withdrawal of blood for transfusion. He reported that such blood, when administered to bleeding patients who did not respond to the usually effective measures, caused cessation of hemorrhage and increase in the level of prothrombin in four hours. Butt and his associates report observations on 3 patients in whom severe hepatic damage was accompanied by deficiency of prothrombin in the circulating blood. They found that prothrombin deficiency cannot be corrected by administration of vitamin K or of whole blood. It also has been shown that administration of so-called fortified blood is not effective in altering the prothrombin level in these patients. Not only was fortified blood of no value in correcting prothrombin deficiency in these patients with severe intrahepatic disease but, likewise, it was ineffectual in the correction of the deficiency in external biliary obstruction, in spite of the fact that the latter condition was quickly remedied by the administration of vitamin K alone.

Carcinoma of Pancreas.—Dashiell and Palmer analyze 90 cases of carcinoma of the pancreas. Pain is an extremely important and early symptom. It was present in 75 of the 90 patients, in all of the 50 in whom there was no jaundice and in 45 of the 60 in whom jaundice was present. The pain, although variable in character, was typically dull and persistent and located high in the abdomen, but occasionally it was referred to the lower part of the abdomen. It was primary in the back in 14 cases and radiated to the back in 22 cases. Jaundice was present in 60 of the 90 patients. In 35 of those with jaundice, the gallbladder could be palpated preoperatively. An epigastric mass was noted in about one third of the patients. Progressive and rapid loss of weight is extremely significant; it occurred in at least four fifths of their cases. Persistent anorexia is of similar importance. Persistent unexplained diarrhea, particularly steatorrhea occurring with abdominal pain, is suggestive of pancreatic neoplasm. Glycosuria, usually inconstant, occurred in 24 of the cases; a diabetic type of dextrose tolerance curve was found in 18 of 21 patients tested. The diagnostic value of this procedure may be greater than has been realized in the past. Roentgen signs of diagnostic importance were noted in nearly half of the series. Greater attention should be paid to the possibilities of roentgen examination as a diagnostic procedure. While there are no pathognomonic criteria for pancreatic neoplasm and the clinical picture is somewhat variable, the essential features are so definite and the procedures mentioned so helpful that the diagnosis should be made earlier and more accurately than at present.

New Management of Otogenic Infection.—Hays and Hall show that in the temperate zone otogenic infections are essentially of two types, a winter type, infections due to gram-positive organisms, and a summer type, infections due to gram-negative organisms. The type caused by gram-positive organisms can be treated adequately with the sulfonamide drugs and the antibiotics. The type characterized by gram-negative organisms does not respond to these drugs. One hundred cases were studied clinically and bacteriologically (160 cultures). It was found that the resistant etiologic agent in chronic suppurative otitis media and external otitis was predominantly Pseudomonas aeruginosa (Bacillus pyocyaneus). In a carefully controlled bacteriologic and clinical study of 100 cases of otitic infections, a new chemical agent, dibromosalicylaldehyde, has been found more satisfactory than other agents suggested thus far. Owing to the unavailability of streptomycin, no opportunity has been afforded to study the efficacy of this antibiotic in these types of aural infections. Dibromosalicylaldehyde ("dalyde") is a readily available, inexpensive chemical agent, which is effective against both bacteria and fungi. It can be utilized in powder, ointment and solution. Seventy-one patients with external otitis were relieved of symptoms within twenty-four hours. In 30 the infection resolved in one week or less, and the rest required two to four weeks' treatment. Although follow-up was inadequate, only 1 patient returned with a recurrence; this one had seborrheic dermatitis. Of 28 patients who had otitis media, 12 had dry ears in two to six weeks; the remainder required up to two and a half months' treatment. Only in 8 did the ears fail to become dry.

*Virus, Nerve Cell and Paralysis: Study of Experimental Poliomyelitis in Spinal Cord. D. Bodian.—p. 1.

Virus, Nerve Cell and Paralysis.—Bodian says that published observations on the histopathologic changes in the spinal cord in poliomyelitis are numerous but the complexity of the problems of pathogenesis has resulted in contradictory interpretations and has left many points unsettled. It was felt that some of the important points remaining at issue perhaps could be investigated more satisfactorily by means of an approach which attempts to correlate pathologic processes in chronologic sequence, with changes in level of virus activity on the one hand and changes in clinical function on the other. It was felt that such an approach requires at least approximate quantitative data at all three levels of observation, and could therefore be essayed only in the experimental animal. In this extensive report Bodian gives a description of the course of a poliomyelitic infection in the spinal cords of rhesus monkeys killed at intervals from the preparalytic period to the chronic stage.

Five Week Penicillin-Oxophenarsine-Bismuth Schedule in Early Syphilis.—The treatment described by Marin and his co-workers consists in the administration of penicillin, oxophenarsine hydrochloride and bismuth compound over a period of five weeks, necessitating hospitalization for the first week. During the first week, the three drugs are given simultaneously. During the four following weeks only oxophenarsine and bismuth compound are given. Sodium penicillin in aqueous solution is administered intramuscularly every three hours, in sixty injections of 40,000 units each. A total dose of 2,400,000 units is thus received in seven and one-half days. Oxophenarsine is given at the rate of four injections of 60 mg. each, every week, for five weeks, the total dose being 1,200 mg. in twenty injections. Bismuth compound, in oil solution, containing 0.07 Gm. of metallic bismuth per cubic centimeter, is administered at the rate of 1 cc. twice a week for five weeks. In May 1945, this schedule of treatment was adopted for cases of early syphilis. Up to November 1947, 230 patients were placed under treatment. Of these, 222 received complete treatment. A total of 201 cases have been kept for final analysis. The 29 others were eliminated because of previous treatment, late syphilis, doubtful diagnosis or delinquency from treatment. There was one fatality due to encephalopathy (0.4 per cent); there were no other severe toxic reactions. Satisfactory progress was obtained in 100 per cent of 36 cases of seronegative primary syphilis, in 90 per cent of 55 cases of seropositive primary syphilis and in 86 per cent of 94 cases of secondary syphilis. The over-all results show 90 per cent satisfactory progress and 4.5 per cent definite treatment failures, with the other 6 per cent pending.

Rutin in Hematuria.—Foucar reports a woman, aged 44, with bilateral congenital polycystic kidneys, gross hematuria, definite impairment of renal function, hypertension and mild secondary anemia. As nothing could be done to improve the underlying lesion, the author decided to try rutin. Twenty milligrams of rutin to which 50 mg. of ascorbic acid had been added was given three times a day with gratifying results. The bleeding stopped promptly. There has not been gross hematuria in six months. The patient feels better than at any time since 1945 and is working steadily. She is also relieved emotionally because of the supression of the visible signs of her disability. Rutin has been used in vascular disturbances particularly of the eyes and may lessen the danger of vascular accidents in hypertension. It may find a place in the treatment of shock, ascites, edema and even some of the eczemas.

Sulfonamide Granuloma.—Williams reports the case of a nurse who noted a tender swelling in her left breast. When application of heat and fomentation failed to resolve the swelling, the lesion was incised and a small bit of tissue removed. At this time sulfanilamide powder was dusted into the wound. Subsequently, the wound became tender and exuded a little serous discharge, healed and again broke down with a small sinus opening. The area was excised with the diagnosis of abscess of the breast. Tissue section showed chronic inflammatory reaction with numerous small areas of granuloma. Repeated subsequent sinus formation required additional incisions. Whereas granulomatous appearance was not found at the original examination of the tissue, such an appearance was found at all three specimens of tissue removed after sulfonamide powder was introduced into the tissues. Reviewing diagnoses for the past year, the author found a dozen reports of reamputations or reoperations in which pain and/or discharge from a surgical scar had been present. In all of the group definite crystalline inclusions were seen in foreign body giant cells. Records of the original operation usually indicated that sulfonamide powder had been dusted into the incision before closure. While the dusting of sulfonamide powder into the wounds at operation may not always produce granulomatous tissue reaction, it remains as unabsorbed foreign material in an appreciable number of cases and provokes a granulomatous tissue reaction.

Radicalness of Methods to Eliminate Colostomy.—Bacon and Rowe performed abdominoperineal proctosigmoidectomy for adenocarcinoma in 146 patients, 78 men and 68 women, between the ages of 32 and 78 years. The extirpated specimen of bowel was sectioned 2, 4 and 6 cm. below the lower edge of the growth. An abdominoperineal proctosigmoidectomy without colostomy was performed in all. This operation was instituted only when the distance between the anal margin and the lower border of the growth was 6 cm. or more. Preservation of the sphincter musculature does not compromise radicalness provided specific principles are carefully adhered to. The radicalness of proctosigmoidectomy compares favorably with other procedures, and in some respects it permits of even wider excision. The survival rate of five and ten year cures is equal to and in some instances betters the results following the abdominoperineal excision of Miles or the perineoabdominal excision of Gabriel. This is true especially when the rate of resectability is considered. Of the 77 patients resected more than five years ago 41 (52.6 per cent) are living and well. In 20 of these 77 patients the histopathologic reports conformed to grade A growth, with 14 of them alive at five years. Proctosigmoidectomy with preservation of the sphincter musculature does not augment the operative mortality; 18 of 376 patients on whom this operation was performed by the authors for cancer died, a mortality rate of 4.9 per cent. The morbidity, immediate and remote, is in no way affected. A consecutive group of 120 patients, 70 men and 50 women, between the ages of 29 and 73, is reported in which the average stay in bed was 6.6 days and the average hospital stay after operation was 13.4 days.

Nonfunctioning Gallbladder.—Bates and King studied 200 patients with chronic cholecystitis who had been subjected to surgical treatment. There were 18 in whom the gallbladder had been poorly or not all visualized and in whom there were no opacities suggesting gallstones roentgenographically. The general incidence of nonfunctional or nonfilling gallbladder was 9 per cent. There were 4 men and 14 women. The average age was 51 years, with about equal distribution in each decade from 30 to 70 years of age. In no case in this series did intravenous administration of the dye give visualization of the gallbladder if visualization had not been obtained after "intensified oral administration" of the dye. A competent radiologist's report of a nonfunctioning or nonfilling gallbladder carries with it the implication of advanced pathologic change, increased morbidity, difficult surgery and increased mortality. Advanced pathologic change was demonstrated at operation in all cases of nonfunctioning gallbladder in this series. Three of the 18 patients died; since there were only 6 deaths in the entire series of 200 patients, deaths in the nonfunctioning group contributed 50 per cent of the over-all mortality rate. The follow-up records of all 15 surviving patients indicate that good results after leaving the hospital may be expected with surgical treatment of the nonfunctioning gallbladder.

Sodium Bismuth Triglycollamate for Dermatoses.—Pascher and her associates studied the therapeutic effects of "bistrimate" (sodium bismuth triglycollamate) in 92 patients with various dermatoses. There were 45 patients with lupus erythematosus, 32 with lichen planus; the other dermatoses included granuloma annulare, psoriasis, scleroderma and other disorders. The therapeutic assay indicates that the drug is a valuable agent in the treatment of the discoid type of lupus erythematosus. The results in this disease may be rated as good to excellent in 50 per cent of the cases, moderate or fair in 25 per cent and poor in 25 per cent. It is more difficult to evaluate the efficacy of the drug in the exanthematic type of lichen planus, particularly because of the variable course of this disease. Subjective or objective improvement was obtained in 40 per cent of the cases. Twelve per cent grew worse or suffered relapse while under treatment. The results are also equivocal in the hypertrophic form of licen planus. The results in the limited number of cases of scleroderma and granuloma annulare allow no inferences but appear to justify further therapeutic investigation. In general the drug is tolerated well. Recovery from the apparently mild toxic effects was complete within a few days to two weeks in all cases in which sodium bismuth triglycollamate had to be discontinued because of untoward reactions.

Total Cystectomy in Vesical Carcinoma.—Ferris and Priestley list the following indications for cystectomy, with the reservation that they constitute merely a working plan on which they have been selecting patients: (1) a low grade lesion with minimal or moderate infiltration, provided it involves a major portion of the vesical wall; (2) a similar type of lesion which is of multicentric origin; (3) repeatedly recurring lesions of low grade; (4) an infiltrating or high grade lesion which cannot be widely removed by segmental resection, and (5) any vesical carcinoma the complete removal or destruction of which would result in serious interference with normal vesical function. Recurrent high grade lesions seldom are suitable for radical surgical treatment because of extravesical extension. Different procedures are employed currently to accomplish removal of the bladder. At the Mayo Clinic, cutaneous ureterostomy has been performed in only 7 per cent of the 111 cases in which total cystectomy has been accomplished for carcinoma in the ten years 1937 to 1946, inclusive. For the most part, procedures other than ureterosigmoidostomy were employed in the earlier cases and have been used less frequently during recent years. It is undesirable to transplant one ureter to the skin and the other to the bowel, as the patient then has the disadvantages of both these abnormal methods of urinary drainage. The authors started to use three stages, transplanting each ureter to the bowel in separate stages and subsequently removing the bladder. Later, 2 stages were employed, a simultaneous bilateral ureterosigmoidostomy constituting the first stage and removal of the bladder forming the second stage. During the past 3 years, 1 stage has been used in the majority of the cases. Thus, in 1946, total cystectomy was performed in 33 cases and in 24 cases a one stage operation was employed. The 1 stage procedure now is the method of choice, but it should not be suggested until familiarity with the operation has been acquired. The hospital mortality rate for 1942 to 1946, inclusive, was 8 per cent, as compared with a rate of 25 per cent for the previous five years, 1937 to 1941, inclusive. The ultimate results depend, to a great extent, on the type of case in which this operation is performed. Whereas 29 per cent of patients survived three or more years after operation, only 19 per cent survived five or more years after cystectomy.

Cystectomy for Infiltrating Carcinoma of Bladder.—Jewett and Lewis discuss the correlation between the exact depth to which the tumor has penetrated the vesical wall and the survival of the patient after cystectomy. Their studies were made on 54 patients. In 41 cases in which the infiltration was deep there were no instances of cure. In 13 cases in which the infiltration was superficial there were only 2 patients who were known to have died of cancer. Three patients have lived over five years without evidence of recurrence of tumor. A preoperative pelvic examination was made and the results recorded in 40 of these 54 cases of cystectomy. In each of 31 cases in which deep infiltration was found microscopically, it had been detected before operation by palpation of a rubbery or stony hard mass in the vesical wall. When rubbery or stony induration was absent on preoperative examination, subsequent microscopic sections always showed superficial infiltration. The over-all end results of total cystectomy cannot be compared with those obtained by conservative procedure, since the conservative methods are often employed in the cases of smaller tumors which are apt to be potentially curable, whereas cystectomy in the past has been reserved for the most part as a heroic measure in deeply infiltrating, extensive and incurable tumors.

Testosterone Propionate in Nitrogen Retention.—Matassarin noticed that when testosterone was used in the treatment of patients with prostatic disorders the nonprotein nitrogen returned to normal more quickly than would have been expected with catheter drainage alone. He used this hormone in 50 cases with reduction of the urea nitrogen. These cases have included both men and women, ranging in ages from 21 to 83 years. They cover a variety of conditions, such as nephritis, prostatis, cholecystitis, heart disease, prostatic hypertrophy, toxemia of pregnancy, postoperative intestinal obstruction and senility. The author hopes that others will study this problem further, both clinically and experimentally.

Benign Pulmonary Histoplasmosis: Familial Incidence.—Weyher points out that whereas earlier reports were concerned with the form which has a grave prognosis, recent reports indicate that there is a benign pulmonary form of histoplasmosis, which is widespread throughout some sections of the United States. The author reports a family group, parents and 3 children, who have lived intermittently in Tennessee. Four of the group are considered to have benign pulmonary histoplasmosis. Although the entire family has been observed for nearly three years, and all members are clinically well at the time of this report, serial roentgenograms of 2 of the children, showing widespread pulmonary calcifications, demonstrate increasing density of the individual areas involved during the period of study. The reactions to histoplasmin in this family and the reproduction of Histoplasma capsulatum are not to be construed as proof of the causation of calcifications shown in the roentgenograms of the chest, since histoplasmin tests are not specific for this organism alone. Clinically the cases appear to fit descriptions of the benign form of this disease. Since no effective therapy exists for the disease, it is suggested that persons with so-called benign cases of the pulmonary form who move away from the areas in which they contracted the infection should avoid returning to the same regions for any protracted stay, especially during the summer months, since apparently reinfection may occur.

Desirability of Routine Use of Tetanus Toxoid.—According to Press, additional information regarding the effectiveness and hazards of active immunization against tetanus has become available during the last few years. Press presents evidence for and against routine active immunization. It was found that about 50 per cent of all injuries leading to tetanus in the civilian population were trivial. The majority of bacteriologic studies revealed that tetanus spores were widely distributed and more frequently found in human feces than in those of horses. The mere presence of tetanus spores in a wound was not sufficient to cause the disease. Statistical evidence shows that less than 20 per cent of the cases of tetanus are reported in the United States. There were at least 910 deaths due to tetanus in the United States in 1940. The conscientious physician, aware of the widespread distribution of tetanus spores, knowing the potentiality of tetanus with trivial injuries and being unable to determine which cases might go on to develop it, would be forced to give tetanus antitoxin for nearly all injuries. In view of the definite effectiveness of tetanus toxoid and its almost complete freedom from adverse reactions, its use seems to be indicated. The not infrequent failure of tetanus antitoxin prophylactically is indicated by the fact that in spite of its use tetanus developed in about 7 per cent of civilian and over 50 per cent of military cases. To avoid the increased risk of anaphylaxis and the more frequent allergic reactions to repeated doses of tetanus antitoxin, it is advisable to give toxoid concurrently with each inoculation of tetanus antitoxin. If this active immunization is then completed, it should be unnecessary to use antitoxin for any future injuries in a person by then sensitized to horse serum. Active immunization against tetanus is indicated. It should be given routinely by private physicians and should also be included in health department programs for all children. The toxoid should be given to children combined with diphtheria or pertussis vaccine, or both. In addition, children who have been immunized for diphtheria and pertussis, but not for tetanus, should have tetanus toxoid available and be encouraged to use it. Adults with increased accident hazards, such as manual laborers in both rural and urban areas, should also be immunized.

Intravenous Ether in Impending Gangrene.—Williams reports on the intravenous use of ether in the treatment of 22 patients with impending ischemic gangrene, diabetic ischemia, arteriosclerosis and hypoplastic ulcer. He used a 2.5 per cent solution of ether—namely, 25 cc. of stock ether to 1,000 cc. of 5 per cent dextrose in distilled water or in isotonic sodium chloride solution—in all of his cases. The 1,025 cc. of solution is given daily, intravenously, the flow being started at 40 drops per minute, and if no reaction occurs, being stepped up to about 50 drops per minute, but not over 60 per minute. He decided that twelve bottles would represent a course, and that he would then give a few days rest, and repeat all laboratory tests before starting on a second course. All patients were thoroughly studied prior to treatment. Blood pressure reading, pulse and temperature records were made during the administration of the drug. Results have been encouraging. Relief from pain has been one of the most gratifying findings. The treatment with ether has not been unpleasant to the patient. It is considered a safe drug in the given dilution. It can be given while the patient is being prepared for operation.

Sulfone Treatment of Leprosy.—Erickson and his associates say that the sulfone drugs have proved to be more effective in lepromatous leprosy than any previous drug tried at Carville. "Promin" (sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate), "diasone" (disodium formaldehyde sulfoxylate diaminodiphenylsulfone) and "promizole" (4,2'-diaminophenyl-5'-thiazolylsulfone) are related chemically to one another by having in common the diaminodiphenylsulfone radical. There is reason to believe that the diaminodiphenylsulfone radical is the active principle, although this has not been definitely established. No claim is made that these drugs are specific remedies for leprosy, but the superiority of the sulfones over chaulmoogra oil is significantly demonstrated by the complete abandonment of the latter treatment in favor of the sulfones at Carville. Objective and subjective clinical improvements are produced by these drugs that cannot be attributed to spontaneous regression of the disease. Improvements are slow in their development but are progressive during treatment. The disease seldom if ever gets worse during treatment. Laboratory examinations indicate a slow but steady decrease in acid-fast organisms in the skin. Negative cutaneous smears and arrest of the disease occur. So far no relapse in arrested cases has been reported.

Gangrene of Legs Following Ligation of Femoral Vein.—Sarnoff reports the case of a man, aged 50, who suffered a heart attack in December 1946 for which he was hospitalized for four weeks. When he was almost well enough to go home he had two attacks of chills. To avoid the possibility of emboli, the attending physician advised ligation of both femoral veins, which was done the following day. Immediately after the ligation both legs became cyanotic, and in the course of the next few days became gangrenous. The patient received a number of paravertebral nerve blocks in the hope of relieving the spasm of the arteries, and thereby helping to establish collateral circulation, but to no avail. Both legs were amputated below the knee. Similar accidents have occurred. They illustrate that ligation of the femoral vein is not to be considered lightly.

Nontuberculous Pulmonary Calcification.—Prior says that in recent years the possible relationship between calcified lesions of the lungs, especially as they occur in the Eastern Central states, and the rare fungus disease histoplasmosis has been a subject of growing interest. Studies in Ohio have confirmed in general this geographic pattern of the incidence of positive histoplasmin reactors. Five thousand and eighty-seven Ohio State University freshmen and student nurses training in Columbus, all of whom were lifetime residents of some one county, were surveyed with roentgenograms of the chest, tuberculin and histoplasmin cutaneous tests. Every county in the state was represented in the group studied. The author believes that in the Eastern Central portion of the United States there is a better correlation between pulmonary calcifications and a positive histoplasmin reaction than with a positive intradermal tuberculin reaction, and in cases of disseminated pulmonary calcification there is an even higher incidence of histoplasmin reactors. This same geographic area in which there is excessive pulmonary calcification with not infrequent miliary distribution corresponds rather closely to both the endemic area of histoplasmosis and the region of high incidence of histoplasmin reactors. The concept of the causation of pulmonary calcifications needs revision. Although many are the result of a true tuberculous infection, calcification may also occur as the result of benign forms of coccidioidomycosis and histoplasmosis or other closely related agent or agents with similar antigenicity.

Transposition of Great Cardiac Vessels.—Miskall and Fraser report the case of a white infant girl with a bifid eighth thoracic vertebra and other defects, who died in the eleventh month. This case typifies one of those cyanotic congenital cardiac defects for which, according to Blalock and Taussig, surgical treatment is of no value. In this anomaly there is an altered relationship of the great vessels to one another and to their respective ventricles in such a manner that the aorta arises from the right ventricle and the pulmonary artery from the left ventricle. The blood is pumped from the left ventricle through the pulmonary artery to the lungs, and it returns to the left auricle through the pulmonary veins. Through the aorta the blood is pumped by the right ventricle to the greater systemic circuit. It returns to the right side of the heart through the venae cavae. In the absence of a septal defect, this condition is incompatible with life since no oxygenated blood can go from the pulmonary to the systemic circulation.

Agglutination of Sheep Erythrocytes by Serum of Patients with Rheumatic Arthritis.—Rose and his associates describe a differential sheep cell agglutination test wherein the agglutination titers of human serum for normal and sensitized sheep erythrocytes are compared. High differential titers have been found to occur almost solely in the serums of patients with active rheumatoid arthritis. Although the nature of the substance and its significance with regard to the rheumatoid state remain to be determined, the present observations indicate that the sheep cell differential agglutination test may be of value in determining the activity status of patients suffering from rheumatoid arthritis. It may also prove to be helpful in the differential diagnosis between rheumatoid arthritis and other diseases with arthritic manifestations, such as rheumatic fever.

Administration of Serum Albumin and Renal Function.—Cargill points out that Thorn and co-workers had noted that the intravenous infusion of concentrated human serum albumin often produces a transient diuresis in patients with nephrosis and Laennec's cirrhosis. These authors studied the immediate effect of rapid injection of a large amount of albumin on glomerular filtration rate and renal blood flow. The clearance technics of Smith, Goldring and Chasis have been followed, using inulin and sodium para-aminohippurate. Rapid intravenous infusion of 75 Gm. of human serum albumin produced a consistant increase in glomerular filtration rate and renal blood flow. These changes were accompanied by both an increased clearance and a decreased tubular extraction of sodium para-aminohippurate. In 2 patients with nephrotic syndrome of chronic glomerulonephritis administration of albumin increased the filtration rate from low to normal levels, and in 1 of these patients it produced considerable diuresis.

Laboratory Infection with Dengue Virus.—Melnick and his co-workers say that in the course of experiments with chimpanzees, human dengue virus was accidentally introduced onto the conjunctival surface of the eye of a laboratory worker. This was followed nine days later by a febrile illness, clinically compatible with dengue. Neutralizing antibodies for the homologous mouse-adapted strain of dengue virus were absent in the patient's serum taken one day after the onset of fever, but were present in high titer in specimens of serum obtained thirteen, twenty-five and forty-five days after onset.

Chemical Pneumonitis Due to Beryllium.—Wilson shows that opportunity for exposure to beryllium starts in the beryl mines. In plants engaged in extracting beryllium from the ore and in the production of beryllium salts and oxides there has been definite evidence of disease among employees. The same has been true in metallurgical plants where beryllium has been used as a constituent in the production of alloys. Cases have been reported in workers coating fluorescent lamps and neon tubes. At least 1 case has arisen in the radio tube industry, and a few where the metal or its oxide was being ground. Beryllium or its compounds may be found in chemical and pharmaceutic plants. It is a possible hazard in research laboratories. Its use has been reported where gas mantles and some ceramics are made. Not all of these industries have experienced the development of pulmonary disease among their workers. In those that have, the symptoms, roentgen pattern and pathologic changes have been so similar that a common denominator is suspected, this denominator being beryllium or one of its compounds. The recognition of the roentgen manifestations of the pulmonary changes in beryllium workers is most important.

Anemia of Cancer.—The studies reported by Schwertman were made on 58 patients with carcinoma of eight common sites. They are based on the initial blood count, hemoglobin and color index. In 10 cases of carcinoma of the breast the average erythrocyte count was 4,300,000 and the color index was 0.98. The presence of metastases in these patients did not noticeably influence the concurrent anemia. In 10 cases of carcinoma of the colon, the average number of erythrocytes was 3,900,000, and the color index 0.9. In 10 cases of carcinoma of the prostate the average erythrocyte count was 4,390,000, and the color index 1.0. In 8 cases of carcinoma of the body of the uterus, the average erythrocyte count was 4,150,000 and the color index 0.92. In 4 cases of carcinoma of the bladder the respective figures were 4,110,000 and 0.95; in 7 cases of carcinoma of the cervix, 3,800,000 and 0.94; in 4 cases of carcinoma of the ovary, 4,001,000 and 0.95, and in 4 cases of carcinoma of the kidney, 4,500,000 and 0.98. In general, anemia is greater when hemorrhage, ulceration and necrosis occur. In some cases, even in the presence of metastasis, anemia does not occur.

Isopropyl Alcohol Intoxication.—McCord and his associates point out that as the industrial demand for ethyl alcohol has increased, isopropyl alcohol has been substituted for it wherever possible. Its use in industry is now widespread and it has become readily available to the general public in the form of rubbing alcohol. The authors present the histories of 3 patients who had ingested rubbing alcohol. In 2 of these isopropyl alcohol was chemically identified. In the third, there was a strong odor of isopropyl alcohol on the breath and in the stomach contents. The action of isopropyl alcohol on man is similar to the action of ethyl alcohol with the exception that coma occurs at lower blood concentrations of isopropyl alcohol than of ethyl alcohol. In 2 cases a profound coma occurred with a blood concentration of isopropyl alcohol of approximately 150 mg. per hundred cubic centimeters. Treatment consisted of gastric lavage, fluids as indicated and symptomatic therapy. Recovery was rapid with no apparent untoward sequelae.

Pancreatic Secretion and Formation of Peptic Ulcer.—Poth and his associates studied the influence of the secretory activity of the pancreas on the formation of ulcers. Sixteen dogs were divided into four groups. Group I served as controls, group II was subjected to total pancreatectomy, group III had the pancreatic ducts ligated and group IV was made diabetic by the administration of alloxan. All of these animals received intramuscular injections of histamine in beeswax. Two control animals which were placed on the same feeding regimen as the dogs operated on had no symptoms of ulcer, and only 1 of them showed an ulcer after forty-five days. When the pancreatic secretion was diverted from the duodenum multiple severe ulcers developed. In both the ulcerations were much severer than have ever been observed in normal animals receiving histamine. It is obvious that the presence of the alkaline pancreatic juice in the duodenum is of great importance in the prevention of ulcers. Although removal of this secretion by extirpation of the gland does not of itself produce ulcers, it is apparent from the results of histamine stimulation that there is a strong predisposition to ulcer formation following pancreatectomy. These experiments do not indicate that diabetes exerts an inhibitory effect on the formation of peptic ulcers. The depancreatized animals were completely diabetic; yet ulcers developed in them just as rapidly and just as extensively as in the animals that had only the pancreatic ducts ligated. The alloxan-diabetic animals showed no lesser tendency toward induced formation of ulcer than did the normal controls. Removal of the pancreas or ligation of its ducts, as is frequently done in surgical procedures on the duodenum or pancreas, is not without danger of postoperative ulceration. It would seem to be advisable to reanastomose the pancreatic duct to the duodenum or jejunum whenever possible after resection of the head of the pancreas. It is doubtful that resection of the vagus nerve at the level of the diaphragm should interrupt a sufficient number of the parasympathetic fibers to the pancreas to alter significantly its secretion.

Aberrant Pancreas in Diverticulum Causing Intestinal Obstruction.—The case presented by De Nicola concerned a boy, aged 13, who suddenly became ill with severe constant pain in the lower part of the abdomen, associated nausea and vomiting, headache, high grade fever and profuse diarrhea. The abdomen was spastic throughout, mildly distended and tender, mostly on the left side. The patient was treated under the diagnosis of severe gastroenteritis, and conservative measures such as chemotherapy, intravenous administration of fluids and intestinal intubation saw him through a stormy course lasting two weeks. The patient had several similar attacks, each requiring hospitalization for weeks at a time. At a fifth attack signs of peritonitis were present and a laparotomy was done. A mass of purulent omentum and gnarled intestine was found low in the midline. The omentum was removed between paired clamps, and four or five loops of intestine were freed during the process. The right iliac fossa was explored and an acutely inflamed and markedly thickened appendix was found and removed. After the operation the patient remained well for several months, but later showed signs of intestinal obstruction. At operation an abscess containing approximately 10 cc. of pus surrounded a perforation in the intestine which was held to the posterior wall by a "nubbin" of tissue. Examination of the specimen removed showed it to consist of a segment of intestine the mucosa pattern of which was like that of the ileum. Heterotopic pancreas was seen in the wall of the intestine infiltrating the submucosal and muscular layers. The intestine and pancreas were both involved in scar and granulation tissue and were infiltrated with polymorphonuclear leukocytes and lymphocytes. Large pancreatic ducts were seen to be dilated as in obstruction. It is probable that the pancreatic ducts became blocked and that resulting cysts became secondarily infected to effect a coalescent abscess which caused both the ileac perforation and the obstruction.

Rupture of Vagina.—Diddle reports 2 women who sustained rupture of the vaginal vault during coitus. Including these 2 cases 133 major tears of the major vault resulting from coitus have been recorded in the past seventy-six years. Thirty-four subjects were previously virginal; 13 were patients having first sexual contact since delivery; 1 woman was pregnant, 8 were postmenopausal and 6 were having the first sexual contact subsequent to some gynecologic operation. Thus friability of tissues incidental to pregnancy and puerperium was etiologically involved in certain women. Two thirds of the tears involved the posterior wall or fornix and only four the anterior wall. Parametrial extension occurred twenty-one times. The peritoneum was exposed thirty times but was broken only six times. Four of these were in girls under the age of 12 years. The rectum was torn in 7, the bladder in 1. Eight incorrect diagnoses were made. They included abortion, carcinoma of the uterus and functional bleeding. Surgical repair was mentioned in 18 instances and tamponade in 20. Twenty-two of 133 patients died. Five of the 22 were young girls not fully mature, and 2 patients were postmenopausal. Seven died of sepsis and 2 of shock due to hemorrhage. Whether sepsis or shock accounted for the remaining mortalities was not ascertained. When vaginal tears involve the upper portion of the organ they may be overlooked because of inadequate visualization. The discussion emphasizes the value and the necessity of examination with a speculum.

*Erb's Palsy. B. Wolman.—p. 129.

Erb's Palsy.—The term Erb's palsy is applied to that type of birth palsy in which the paralysis, or paresis, is confined to muscles supplied by the fifth and sixth cervical nerves. The deltoid, supraspinatus, infraspinatus, teres minor, biceps, brachialis, brachioradialis and supinator muscles are usually involved in cases of severe disease, whereas in cases of mild disease only some of these muscles are involved. Wolman reviewed the cases seen at the outpatients' department of a busy provincial teaching hospital during the last twenty-one years. Actually 125 persons with Erb's palsy presented themselves during that time, but the author has only been successful in tracing and interviewing 37 of this group. Injury at birth to the supraclavicular portion of the brachial plexus is the accepted cause of the condition. Skilled obstetric technic in delivery, particularly in the use of forceps, is the main factor in avoiding this paralysis. Large babies are more likely to be injured. A large child in a primigravida needs special care with the delivery of the head and arms. Treatment must be carried out from birth. Infants treated within the first month do well and results are 100 per cent successful. If treatment is delayed, contractures causing impaired function of the shoulder and elbow will develop quickly. The treatment consisted of adequate splintage, associated with massage, together with exercises in older children.

Microgliomatosis.—Russell and her associates point out that Hortega and others have shown that the microglia represents the reticuloendothelial system in the central nervous tissue. The authors present a series of 7 cases of cerebral tumor in which the proliferating cells were predominantly of the microglial type. In 3 cases the cerebral tumors were associated with lesions of similar structure in other organs. It is considered that the character of the lesions in the brain and other organs justifies the classification of the condition as reticulosis. The authors cite a number of reports from the literature in which tumors are described which were similar to those in this series. It has been stated by some authors that tumors described as microgliomas are either gliomas or sarcomas, infiltrated by microglial cells. Such a view is untenable in the face of the evidence provided by the cases reported here. First, the existence of two tumors in which the great majority of the cells appeared to be impregnated and which showed proliferation of mature microglial cells at a distance from the main tumor; secondly, the presence in 3 cases of similar lesions in the spleen, lymph nodes and other tissues, and, thirdly, the gradation of intensity in the silver staining of the proliferating cells provide convincing evidence that these specimens are tumors of reticuloendothelial elements.

Prognosis in Carcinoma of Breast.—Patey and Dyson compare the results of different combinations of surgical and irradiation treatment of carcinoma of the breast in a series of 118 patients treated between 1939 and 1943, and followed up until the end of 1946. He concludes that until an efficient general agent for the treatment of carcinoma of the breast is developed, a high proportion of patients are doomed to die of the disease whatever combination of surgical treatment and irradiation is used, because in a high proportion of cases the disease has passed outside the field of local attack when the patient first comes for treatment. A modified radical operation in which the pectoralis major is preserved shows results as good as those of the standard radical operation, and in addition has positive advantages. Wider sacrifice of skin with subsequent skin grafting is desirable to reduce the incidence of local cutaneous recurrences, which is still disconcertingly high. Partial mastectomy combined with axillary dissection may be justifiable in occasional early cases with small growths, but is unjustifiable as a routine, owing to the danger of local recurrence. Simple mastectomy combined with irradiation to the axilla may give a satisfactory result, but the irradiation is generally more upsetting to the patient than surgical dissection of the axilla.

Pleuropneumonia-like Organisms in Nongonococcic Urethritis.—Harkness and Henderson-Begg say that a number of organisms of the same group, usually referred to as pleuropneumonia-like or "L" organisms, have been described as causing arthritis, abscesses, pneumonia, "rolling disease" and other diseases. In recent years organisms of the group have been identified in the urogenital tracts of both men and women. The authors attempted to correlate the findings of pleuropneumonia-like or "L" organisms on culture with the different types of nongonococcic urethritis. Pleuropneumonia-like organisms have been cultured from 21 of 57 cases of subacute abacterial urethritis and from 5 of 10 cases of acute abacterial urethritis. "L" organisms were cultivated from urethral washings in 7 of 41 cases of arthritis complicating abacterial urethritis (so-called Reiter's disease). All cultures of joint fluid, blood, conjunctival secretion or cutaneous lesions were negative. "L" organisms were recovered from 2 of 74 cases of bacterial urethritis (nongonococcic), 2 of 16 cases of abacterial pyuria, 12 of 46 cases of nongonococcic cervicitis or vaginitis and 15 of 157 cases of acute gonorrhea. Fifty normal males and 15 normal females were also examined, but in no case were "L" organisms recovered. Serologic investigations—agglutination and complement fixation—carried out on all suitable cases at varying stages of the disease were invariably negative in result. Thus, although evidence from cultures has favored the view that "L" organisms are etiologically related to certain types of abacterial urethritis, abacterial pyuria and possibly Reiter's syndrome, serologic tests have not supported this conclusion. Negative serologic reactions, however, cannot be regarded as strong evidence against the incrimination of "L" organisms in the causation of these diseases.

Valvulotomy for Congenital Pulmonary Stenosis.—The immediate results of the Blalock-Taussig operation can be dramatically successful, but two possible drawbacks suggest themselves: (1) that the fistulous communication may not grow with the child and thus will prove ineffective in later years; (2) that an arteriovenous leak or artificial ductus arteriosus is created—a condition for the relief of which, when it occurs as a congenital maldevelopment, an operation has been considered necessary. The relief of the obstruction itself would answer the greatest objection: An increased supply of blood would be provided to the lungs without the disadvantages of an arteriovenous leak. It is usually stated that the stenosis in these cases is almost invariably subvalvular or infundibular and is therefore not amenable to relief. This is not so; a number of patients with Fallot's tetralogy have valvular stenosis either with or without subvalvular stenosis; moreover, cases of morbus caeruleus occur in which a pure pulmonary valvular stenosis is present. The best way to assess the state of the valves is to inspect them under direct vision. The author describes 3 cases which show that pulmonary valvulotomy is a feasible operation, and all 3 patients have survived the procedure. The result in the first has been moderately successful so far; in the second the result is good; in the third it would appear to be good, but is as yet indeterminate functionally. The ages of the patients were 18, 11 and 23 years, respectively. Thus 2 patients were of an age when the prognosis is ordinarily poor. Far better results are to be anticipated in younger patients. The vascular complications are disturbing. The first case teaches that a careful watch must be kept for signs of peripheral arterial embolism after cardiotomy so that immediate embolectomy can be considered. Arterial thrombosis occurs also with the Blalock operation. Presumably it is most likely to occur when the blood pressure falls, especially in the presence of polycythemia. Much still remains to be done in the treatment of "blue children" with pulmonary stenosis, but the results are encouraging enough to justify proceeding further. This operation is not meant to supplant the Blalock operation. It is of use in only a small proportion of cases. Until a method can be found to relieve the subvalvular stenosis, the Blalock operation must continue to take precedence.

Efficacy of BCG Vaccination.—Malmros points out that last year hundreds of thousands of young children and adolescents in war-ravaged Europe were given tuberculin tests and that the nonreactors were vaccinated against tuberculosis with BCG. The statistically most trustworthy method of determining efficacy, that of vaccinating alternating patients, had to be abandoned in Scandinavia. In the author's district of Oerebro, Sweden, which has about 230,000 inhabitants, vaccination with BCG has been done extensively since 1942. Practically all the newborn are vaccinated. The whole population is gradually tuberculin-tested and the nonreactors are vaccinated if they give their consent. So far, 22,413 persons have been vaccinated, 8,040 being newborn infants, 7,836 children over 1 year, and 6,537 adults. When a patient is admitted to any hospital with the diagnosis of tuberculosis or suspected tuberculosis it is ascertained whether the patient has been vaccinated with BCG. By this means it is possible to find out whether any of those vaccinated have contracted tuberculosis. From 1942 to 1947 only 1 such case was discovered. The harmlessness of BCG is established beyond doubt. If Wallgren's method is used and the vaccine in a dose of 0.05 mg. is injected strictly intracutaneously, large abscesses seldom appear (0.8 per cent). Small abscesses occur in about 7.8 per cent. They heal relatively quickly. In newborn infants abscesses occur much more rarely (2.3 per cent) than in older children and in adults. The author states that the BCG campaign should not be confined to the newborn, but that whenever a nonreactor is encountered he ought to be vaccinated.

Lymphatic Connections in Subarachnoid Space.—Field and Brierley say that suggestions have been made that infective agents, particularly the virus of poliomyelitis, may extend to the central nervous system along certain ill defined lymphatic pathways. The elucidation of direct anatomic pathways, particularly those between the spinal subarachnoid space and the abdominal lymphatic system, is taken up in this paper. After an outline of the salient features that have been presented in the literature, experiments on rabbits are described. Diagrams illustrate the mode of elimination of india ink particles from the subarachnoid cul-de-sac around the dorsal root ganglion of a spinal nerve; also from the subarachnoid extensions along the olfactory nerves. In both cases ink particles are eliminated from the subarachnoid space into interstitial tissue and pass secondarily into the lymphatic system. The nasopharynx, tonsil and upper respiratory tract have all been implicated from time to time as portals of entry for virus. The results presented here have substantiated the existence of a definite anatomic pathway (in the rabbit) between the cranial subarachnoid space and the deep cervical lymph nodes by means of lymphatics which emerge through the jugular foramen. Since the tonsil, too, is connected with these nodes, the anatomic basis exists for lymphatic extension of virus from tonsil to cranial subarachnoid space. This connection is in addition to the more readily demonstrable paths from the nasal mucosa. The author also describes retrograde lymphatic flow to the cord. The prevertebral lymph nodes are the "regional" nodes of the spinal subarachnoid space. The presence of virus in the cerebrospinal fluid in human and experimental poliomyelitis would seem to be uncommon. In view of the rapidity with which particulate matter has been shown to be eliminated from the subarachnoid space, it is probable that reports in the literature are concerned with stages when virus, which has been present earlier, has already been eliminated. The distribution of fine particulate matter in the cerebrospinal fluid has been compared with that of the early lesions of poliomyelitis, and certain similarities have been noted suggesting that the fluid may play a more important part in the pathogenesis of the condition than that usually accorded it by adherents of the theory of neuronic transmission.

Epidemiology of Poliomyelitis Outbreak.—Sweetnam presents studies carried out in the course of an outbreak of poliomyelitis in Eccles in 1947. This borough had the highest attack rate of any district. There were 46 cases, giving an attack rate of 1.09 per thousand of the population. The case mortality was 6.5 per cent. The incubation period was seven to thirteen days. Only one family had more than 1 frank case. There was only 1 instance of a case to case contact. The epidemic was confined for nearly six weeks to the western half of the borough by a canal which restricted communications.

The results of field studies indicated that the chief factor in the spread of infection was human contact, in which abortive cases and healthy carriers played the major part. The presence of the virus in the nasopharynx of patients and carriers was of much more importance for the spread of infection than was its presence in feces A survey revealed the presence of numerous abortive cases, especially in close proximity to frank cases, and suggested that of every 20 cases in which clinical signs and symptoms of infection were evident less than one developed into a paralytic case. Suggestions to improve the present system of notification are made, particularly the necessity for notifying abortive cases.

Neonatal Meningitis Due to Escherichia Coli.—According to Duval and Burrowes meningitis due to Escherichia coli is relatively more common in the newborn than in childhood or later life. The original portal of entry is difficult to determine, but there are indications that infection may enter at any of many sites. The following portals of entry have been mentioned: middle ear, intestine, lungs, genitourinary tract, spina bifida, umbilicus and morbid conditions of skin, scalp, mucosae and subcutaneous tissues. In addition, transplacental bacteremia, possibly arising from maternal pyelitis, has been suggested. Aspiration of amniotic fluid infected with Esch. coli, causing bronchopneumonia followed by spread through the blood stream to the meninges, has also been suggested as a portal of entry and seems to have been the route of infection in the fatal case reported here. The infant was 3 days old. The mother had intrapartum eclampsia and prolonged labor and on the third day of the puerperium contracted pyelitis due to Esch. coli and endometritis.

Control of Infection in Burns.—Colebrook says that at the Birmingham Accident Hospital an attempt has been made to treat burns under conditions which aim at eliminating not only the "contact" infections (from hands, instruments), but also air-borne infections. Most of the sepsis of burns is due to infection in the hospital and can be prevented if the right conditions and the appropriate routine are established. Two distinct objectives have to be kept in view: (1) blocking the transmission of pathogens to the burns at the time of the dressing, and (2) blocking their transmission to the burns between one dressing and the next. The first of these objectives has been successfully attained during the three year period in the burns unit at the Birmingham Accident Hospital (734 patients treated) by having all dressings done by a trained team using a strict aseptic technic in a room ventilated by an abundant stream of filtered air. The number of patients infected with hemolytic streptococcus and pyocyanea at the time of dressing under these conditions has been less than 1 per cent. The second objective has proved much more difficult. The majority of the infections transmitted between one dressing and the next occurred in patients whose burns were difficult (or impossible) to cover adequately with dressings, or in patients who interfered with their dressings. When dressings become soaked with serous exudate during the first few days after burning, pathogens conveyed to the outer bandages from the air or from bedding are able to "grow through" the dressing and so infect the burned surfaces. The use of cellophane as a bacterial barrier to prevent this is suggested. Streptococcic infections have proved the easiest to control because they can be quickly eliminated from the burns by local application of penicillin (or of sulfonamide compounds). In view of the manifold opportunities for cross infections presented by a large ward and the highly infectable nature of burns, it is concluded that the best way to maintain a high level of freedom from hospital infection would be to nurse all burns during the first few weeks in well ventilated cubicles, each containing a single bed.

*Multiple Streptococcal Abscesses of Liver: Recovery with Penicillin. H. S. Morley.—p. 949.

Repair of Large Hernias with Tantalum Gauze.—Douglas describes reactions in rabbits in which sutures of tantalum, stainless steel, "inconel" (composed of 80 per cent nickel, 13 per cent chromium and 7 per cent iron), silver, black silk and surgical gut were implanted in the abdominal wall. It was found difficult to compare the tissue reactions to various suture materials because of the variation in response from animal to animal. Sutures of tantalum, stainless steel and "inconel" are associated with less tissue reaction than those of silk or of silver. The tantalum gauze which Douglas investigated was woven from tantalum wire of a diameter of 0.075 mm. It is sufficiently pliable to adapt itself to the movements of the abdominal wall. Segments of tantalum gauze were substituted for the whole thickness of the abdominal wall of rabbits and the repair was examined after 175 to 375 days. When an attempt was made to dissect the gauze from the abdominal wall, it became evident that the connective tissue fasciculi had grown through the meshes of the gauze. The tantalum gauze was used also in the repair of 32 large hernias in patients. These patients appear to have more pain in the first few postoperative days than do those who have had other types of repair. This may be due to the extensive dissection needed to obtain an adequate overlap. Of the 32 wounds, 3 became infected, whereas the others healed by primary union. The infected wounds all healed satisfactorily. One of the patients died of cerebral thrombosis three months after operation. All the other patients are in good health and have no complaints referable to the operation. The scars are soundly healed, soft and mobile, and the hernia has not recurred.

Penicillin in Multiple Streptococcic Abscesses of Liver.—Morley presents the case of a woman, aged 56, whose symptoms were considered as indicative of an anterior subphrenic abscess. At operation an enlarged liver presented itself, with surface studded with yellow raised areas, the mass felt being one of these. Aspiration yielded creamy pus which contained large numbers of streptococci. Penicillin, 100,000 units, was given forthwith, and thereafter 60,000 units every three hours for eleven days to a total dose of 4,060,000 units. On the third day of penicillin therapy temperature reached normal. The patient's general condition improved with unexpected rapidity, her pain subsided and her recovery was uneventful. Her doctor reported five months later that she was in perfect health.

Nitrogen Mustards in Hodgkin's and Other Diseases.—Iversen and Kjerulf-Jensen review observations on 21 patients who were treated with methyl-bis-(beta-chloroethyl)-amine-hydrochloride. The results were excellent in 6 cases of polycythemia vera. In 3 cases of multiple myeloma pain decreased, while in 5 of 9 patients with Hodgkin's disease symptoms were relieved, although this effect was only temporary.

Treatment of Subacute Endocarditis.—Seventeen patients with subacute bacterial endocarditis were treated by van Goidsenhoven and de Moor between September 1944 and June 1947 with penicillin alone or in combination with other therapeutic measures. As of Jan. 1, 1948, 12 of these patients are alive; 8 of these have completely recovered without signs of cardiac failure; in 3 the cardiac function has deteriorated more and 1 shows severe cardiac failure but no signs of infection. For 2 of the 5 patients who died, the treatment was not sufficient, because of the shortness of the supply of penicillin (in the period 1944-1945); in 1 case the treatment started too late (after one hundred and thirty weeks' evolution). The last 2 cases proved refractory to a normally adequate treatment. The authors propose as a routine treatment: for the first two days twelve to sixteen times 100,000 or 200,000 units of penicillin in twenty-four hours; for a period of four weeks eight times 100,000 units of penicillin per day and, finally, a two week period with eight times 50,000 units per day. If symptoms of infection do not disappear with this treatment and the blood cultures still remain positive, the therapeutic plan has to be completely modified. The doses will then be based only on the in vitro sensitivity of the isolated germs and on the penicillin levels in plasma.

*Diastolic Extra-Sounds and Gallop Rhythm: Graphic Characteristics, Frequence, Clinical Importance and Audibility in Normal Persons and Cardiac Patients. A. A. Luisada and M. Roitman.—p. 345.

Diastolic Adventitious Sounds and Gallop Rhythm.—Luisada and Roitman studied 111 phonographic tracings of 90 persons, either normal or with cardiac disease, at the Instituto de Cardiología of Mexico. Adventitious sounds were encountered in 72 per cent of normal persons and in 52 per cent of patients with cardiac disease. Gallop rhythm was found in 28 per cent of the former and in 48 per cent of the patients with cardiac disease. Having found that no single criterion is sufficient for differentiation of adventitious sounds from gallop, they established the following arbitrary rule as a result of the study: (*a*) A vibration having a frequency of 30 or more per second was called gallop whatever its height. In almost all such cases the height was found to be two thirds or more that of the normal heart sounds. (*b*) A vibration having a frequency of less than 30 per second was considered a gallop only if its height was greater than two thirds of that of the normal heart sounds. (*c*) A vibration having a frequency of less than 30 per second and a height lower than two thirds of that of the normal heart sounds was considered as an adventitious sound. Comparison between clinical auscultation and phonocardiographic findings reveals that no relation exists between them. The multiple causes of error inherent in clinical auscultation emphasize the importance of phonocardiography. While adventitious sounds and gallop rhythm are more frequent in cardiac patients than in normal persons, they may be found occasionally in the latter, as their production is favored by functional elements which may be present in the absence of heart disease and among which tachycardia is one of the most common. The phonocardiographic classification proposed does not separate physiologic from pathologic cases even though it facilitates grading of the severity of the functional disorder of the heart. There are gallops which are inaudible, and their detection by phonocardiography is important for complete evaluation of the clinical data.

Coagulation Defect of Hemophilic Blood. W. Meier.—p. 304.

Pathogenesis of Löffler's Syndrome.—A review of the literature convinced Löffler and his associates that so far no indisputable proof has been furnished that ascariasis is the cause of the evanescent pulmonary infiltrates with eosinophilia first described by Löffler in 1932. A number of investigators, including Löffler, found that it is a causal factor in some of the cases. In this report the authors describe animal experiments which were designed to clarify the question regarding the causal significance of ascariasis. A total of 48 guinea pigs was used in two experiments. It was possible to reproduce in every detail the syndrome of evanescent pulmonary infiltration with eosinophilia, and it was possible to corroborate the observations of other research workers. The authors were able to demonstrate the larvae of Ascaris in eosinophilic infiltrations. Their pathologic observations confirm the observations made by von Meyenburg and Nagel in human subjects. The authors direct particular attention to the hitherto ignored atelectasis, which is important in the pathogenesis of the evanescent pulmonary changes. They also stress that the localization of the eosinophilic infiltrations does not permit conclusions regarding the portal of entry or the nature of the causal agent.

Cold Temperature and Takata Reaction.—The observation that the Takata reaction was more frequently positive during the cold season induced Baur to study this reaction under refrigerator temperatures (average of plus 3 C.). It was found that cooling healthy subjects or their blood for a short time had no influence on the outcome of the reaction. In cases of parenchymal disease of the liver verified at necropsy the Takata reaction was occasionally negative when the test was done at room temperature, but became positive when it was done at refrigerator temperature. Furthermore, in the course of hepatic disease the "cold" Takata reaction becomes positive sooner and remains so longer than if the test is done at room temperature.

*Urethane in Treatment of Acute Leukemia in Childhood. R. F. Landolt.—p. 232.

Urethane in Leukemia of Children.—Landolt reports studies on 16 children who ranged in age up to 11 years, and who had acute leukemia. The children were treated with urethane, which is an ethyl ester of carbamic acid. The substance was given orally or by rectum in doses of 1 to 3 Gm. per day. Except for isolated cases of vomiting, there were no unpleasant secondary effects. The leukocyte count dropped to 500 or less within from five to ten days. The proportion of neutrophils rose considerably in some cases, but only rarely would a small absolute increase be shown. Increased erythropoiesis in the bone marrow was noted in 5 of the children; in 4 of these it was slight and in 1 great. There seemed to be an increase in the number of mitoses under the influence of the urethane. The swelling of the liver, spleen and lymph nodes decreased in 10 of the patients, in some of them decidedly, and there was a simultaneous improvement in the general condition. The favorable effect on the clinical state was only temporary. In one patient all leukemic changes subsided and panhemocytophthisis developed. Four other cases showed the same tendency, without, however, reaching a point where complete regression of the extramedullary leukemic foci occurred. Urethane apparently can damage erythropoiesis and thrombopoiesis. Urethane therapy can be recommended in acute leukemia, since improvement can take place, but it is necessary to check the blood picture so that the preparation can be discontinued before panhemocytophthisis sets in. The author recommends simultaneous employment of penicillin, in order to prevent infection, and advises frequent blood transfusions to counteract the development of panhemocytophthisis.

*Statistics of Infectious Endocarditis Treated with Antibiotics (Penicillin and Streptomycin). P. Sédallian, P. Monnet, M. Vialtel and R. Maral. —p. 453.

*Acute Miliary Tuberculosis Treated with Streptomycin. P. Sédallian, J. Moinecourt, M. Vialtel, R. Maral and others.—p. 461.

Antibiotics in Infectious Endocarditis.—Sédallian and his co-workers treated 24 patients with infectious endocarditis by intramuscular administration of penicillin and treated 6 additional penicillin-resistant patients with streptomycin. Eighteen patients recovered and there were 12 failures including 11 deaths and 1 patient whom the persistent infection induced to leave the hospital. Pending laboratory results, treatment should be instituted with large doses of penicillin (1,000,000 to 1,500,000 Oxford units). In cases with negative laboratory results the same high doses should be employed for at least ten to fifteen days, and then should be reduced according to the improvement obtained. The dose should be based on the results of the laboratory tests; it should insure a blood level three or four times superior to that of the microbic resistance. Duration of the treatment depends on the symptoms and their clinical evaluation. In 7 of 8 patients with negative blood culture the treatment failed, but 3 of 4 in whom penicillin was ineffective recovered when streptomycin was given. Penicillin was effective in 13 of 15 patients with Streptococcus viridans. A temporary resistance to penicillin subsided in some of these cases after temporary discontinuation of the drug: with this method the prospects are better than when progressive doses are employed, which will only exaggerate the resistance to the drug. Penicillin was ineffective in 3 cases with Enterococcus, but in 1 of them recovery was obtained with streptomycin. Synergistic action of penicillin and streptomycin was not apparent in any of the authors' cases. Streptomycin is indicated for cases in which an acquired resistance to penicillin is due to insufficient treatment.

Streptomycin in Miliary Tuberculosis.—Sédallian and his co-workers treated 49 patients with miliary tuberculosis with streptomycin. None of them presented any meningeal symptoms on admission to the hospital. In 17 the disease was severe, with high grade fever, dyspnea and cyanosis. Twenty patients had fever of long duration without pronounced functional symptoms. Twelve patients had afebrile miliary tuberculosis or were running a temperature around 38 C. (100.4 F.). Thirteen patients had genitourinary lesions; 9 had laryngeal lesions, and 26 had pulmonary lesions. Results showed that the patients remained tuberculous and the course of their disease differed according to its localization, as it did before streptomycin was instituted: the genital lesions showed a tendency to total or subtotal regression, particularly in women; the pulmonary lesions showed a tendency to stabilization, to cavity formation, fibrosis or caseation depending on the case. The streptomycin cicatrized the laryngeal lesions, reduced the pulmonary congestion or perifocal inflammation and was responsible for the disappearance of the minute tubercles in the roentgenograms. Koch's bacilli did not disappear; their caseating and fibrotic effect was not changed. Their behavior seemed to depend on the normal reaction of the various tissues. The disappearance of the minute tubercles in the roentgenograms is only an episode in this diffuse hematogenous disease which threatens the meninges. Proper dosage and continued treatment for three to four months may be life saving in those cases in which the meninges were not yet involved when treatment was instituted. Early symptoms must be watched for, and ophthalmologic signs are of great importance because lumbar puncture is not without risk.

*Uremia as Result of Sodium Chloride Deficiency in Pregnancy and Puerperium. G. A. Lindeboom.—p. 1384.

Advisability of Sulfonamide Drugs in Tonsillitis.—Voet compared two groups of patients with tonsillitis, one of which had been treated before the time sulfonamide drugs were generally used and the other was treated with sulfonamide drugs. No shortening of the duration of the disease or of the fever could be noted in the patients who had been treated with sulfonamide compounds. The author warns against routine chemotherapy in patients with tonsillitis, for not only is there a danger that toxic effects and hypersensitivity might develop, but the bacilli may become resistant to chemotherapy, and thus the sulfonamide compounds may lose their effectiveness.

Uremia After Salt-Deficient Diet in Pregnancy.—Salt-free or salt-deficient diet is often prescribed for pregnant women, particularly if edema or increase in blood pressure suggests a possible renal defect. The author presents the histories of 4 women, which indicate that deficiency in sodium chloride may lead to uremia in pregnant or puerperal women. One of these women had been subject to hyperemesis throughout her pregnancy. The other 3, however, had been on a salt-free diet. These cases demonstrate that a salt-free diet, although helpful in some cases, is not entirely without danger, particularly if it is continued over long periods. The renal function becomes impaired by the sodium chloride deficiency and the complete restoration may require months.

Critical Viewpoints Concerning Palliative Resection in Duodenal Ulcer. S. Lindgren.—p. 1084.

Blood Findings in Juvenile Amaurotic Idiocy.—Blood studies of 6 patients with this disorder revealed abundant vacuole formation in the lymphocytes in cytoplasm otherwise apparently normal. Vacuolated lymphocytes, van Bagh and Hortling state, were fewer in recent cases than in those of longer standing. In the sternal punctate, without other pathologic cell elements, the vacuolated lymphocytes were less numerous than in the peripheral blood. Attempts to stain the vacuoles by different staining methods failed. The vacuoles did not appear in dark ground illumination. The occurrence of highly vacuolated lymphocytes is believed to be significant in the establishment of juvenile amaurotic idiocy. The vacuolation is assumed to be due to a disturbance in the vital function of the mature lymphocytes, possibly dependent on disturbance in lipid metabolism.

Sensitiveness to Penicillin. H. K. Kristensen.—p. 1224.

Treatment of Cold Feet and Legs After Poliomyelitis.—Stenport says that cold feet and legs, with blue discoloration of the skin, are a frequent sequel of poliomyelitis. Treatment with a vasodilating substance, 2-benzylimidazoline hydrochloride ("vasodil") was carried out in 1944 in a large number of cases and as a rule resulted in a more or less transient sensation of warmth. After preliminary blocking of the second and third lumbar ganglions with 1 per cent procaine hydrochloride showed positive results, sympathectomy of the second and third lumbar ganglions was done in 90 cases from 1945 to 1947 with good primary results both subjectively and objectively. The surgical treatment is reserved for cases with pronounced vasospastic changes in which repeated treatment with the drug is ineffective and in border cases in which this treatment gives only partial relief.

*Some Problems Involved in Treatment of Abscess of Lungs with Intrabronchial Penicillin. H. Métras, M. Grégoire, J. Lieutier and C. Gaillard.—p. 471.

Intrabronchial Penicillin in Pulmonary Abscess.—Métras and his co-workers treated 60 patients with pulmonary abscess with penicillin by intrabronchial route. In cases of severe disease it was combined with systemic penicillin therapy, 1,000,000 units per day. Recovery from pulmonary abscess may be considered complete (1) with the disappearance of functional symptoms and return to health as demonstrated by bronchography within six months after last subjective symptoms; (2) with mild roentgenologic or bronchographic sequelae within two years after last functional symptoms, and in the absence of hemoptysis and expectoration. Recovery of the first type was obtained in 30 patients and of the second type in 15 patients; i. e., 75 per cent recovered, while 15 patients (25 per cent) failed to recover, 6 because of extrapulmonary causes. The remaining 9 patients had recurrence after penicillin was discontinued; they required pulmonary surgical treatment, which is probably less dangerous after treatment with penicillin. Results of intrabronchial penicillin treatment for pulmonary abscess are superior to those of pneumonotomy reported by Neuhof and Tourrof in 1944.

*Chemical Pregnancy Test: Determination of Sodium Pregnandiol Glycuronidate. R. Rivoire and G. Bueil.—p. 1634.

Electroencephalography in Diagnosis of Epilepsy in Children.—Cornil and his co-workers made electroencephalograms of 184 children between the ages of 6 and 13 years, 138 of whom had clinical epilepsy, while in 46 the epilepsy was doubtful from the clinical point of view. A typically normal tracing, taking into account the age of the child, furnishes a presumption against the diagnosis of epilepsy, but does not provide definite proof. Positive diagnosis is made in the presence of two conditions: (1) when during rest one observes paroxysmal waves characterized by considerable amplitude, by their rhythmicity and sometimes by their regularity. Jasper's term of "hypersynchronic rhythm" seems to be appropriate because these rhythms are very likely due to an excessive synchronization of the cortical neurons; (2) when one observes a slow dysrhythmia which is incompatible with the age of the patient, in a child with nervous attacks of a definite or nearly definite epileptic nature. Electroencephalographic confirmation of the diagnosis of epilepsy was obtained in 90 per cent of the patients in whom clinical diagnosis of epilepsy was made. Probability of epilepsy is suggested every time when a definitely pathologic tracing has been obtained which is not specific for epilepsy in a child presenting nervous attacks the epileptic nature of which has not been established clinically. Such pathologic tracings are represented in general by a slow dysrhythmia incompatible with the age, or by continuous or paroxysmal slow hypersynchronous waves which may be elicited by hyperpnea in a child with considerable glycemia. The possibility of an epileptic process should be considered when one observes a pathologic nonspecific tracing in a child presenting nervous attacks whose epileptic nature appears unlikely from the clinical point of view.

Necrotic and Suppurative Forms of Pulmonary Cancer.—According to Poinso and his co-workers, the destruction of the pulmonary tissue and the resulting suppuration which occur in the course of primary cancer of the lung may be explained by the obstruction of the bronchial arteries due to the accumulation of cancerous cells. These necroses occur particularly in cases in which the tumor is located in the hilus. The necrosis may result in formation of a cancerous cavity, or it may be limited to the periphery of the cancer, for which the term extraneoplastic necrosis is suggested. The latter type is responsible for the large suppurative ulcerations which may involve one or several lobes. Infection may be limited or completely absent, and that confirms the necrotic origin by obliteration of the bronchial arteries. When infection is present, it is limited to the peripheral crown of the destroyed zone, and therefore may be considered as secondary. In case of primary infection a massive polynuclear reaction should have been observed in the center of the destroyed area, but was not in the cases studied by the authors.

Sodium Pregnandiol Glycuronidate Test for Pregnancy.—Rivoire and Bueil describe a new rapid and simple technic for the determination in the laboratory of sodium pregnandiol glucuronidate, half the amount of the urine excreted within twenty-four hours (about 500 Gm.) and iso-amylic alcohol for the extraction being used. The final determination is made by nephelometry. The determination of sodium pregnandiol glucuronidate is an excellent test for pregnancy. It has the advantage of not requiring animal experiments. It is as valuable as Friedman's test, the performance of which may require forty-eight hours as compared with three quarters of an hour for the pregnandiol test. In gynecology the usefulness of the determination of sodium pregnandiol glycuronidate is of the first order, but its utilization is limited by material difficulties because repeated analyses are indispensable for the complete exploration of the menstrual excretion of pregnandiol.

*One Case of So-Called "Voluntary" Acceleration of Pulse with Reverse Accentuation of Cardiac Sounds. F. Scheminzky.—p. 398.

"Voluntary" Acceleration of Pulse.—Scheminzky reports a man between 40 and 50 years old presenting himself at the Vienna Physiologic Institute for demonstration, who was able to bring some of his skeletal muscles into action and who could influence at will his heart beat. By word of command such as "quicker" or "slower" he gradually produced changes in the pulse rate. During tachycardia the pulse rate was increased to double that during rest, reaching a maximum of 123 per minute. Slowing of the pulse rate was manifested as diminished tachycardia, and the minimum reached varied from 57 to 51 per minute and was not much below the starting point at the beginning of the experiment. During bradycardia, on complying with the command "slower," Valsalva's experiment was always associated with a reversion in the accentuation of the cardiac sounds: it was always the first cardiac sound which was louder, while the second cardiac sound was louder and therefore more accentuated during rest and during tachycardia. The reversed accentuation of the cardiac sounds, a sequel of the impaired filling of the heart during bradycardia, is of interest with regard to the pathogenesis of the first cardiac sound in mitral stenosis.

Book Notices

Medical Hypnosis. Volume I: The Principles of Hypnotherapy. Volume II: The Practice of Hypnotherapy. By Lewis R. Wolberg, M.D., Assistant Clinical Professor of Psychiatry, New York Medical College, New York. Fabrikoid. Price, $5.50; $6.50. Pp. 449; 513. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

This book represents probably the most thorough, comprehensive, up-to-date exposition on the history, technic, applications and therapeutic goals of hypnosis published up to the present time. In the preface to volume I, the author states: "Few therapies in the history of medicine have enjoyed simultaneously such widespread acclaim and such universal condemnation as has hypnosis. To some extent these opposing attitudes still prevail. However, recent years have witnessed advances in experimental and therapeutic hypnosis which have tended to establish hypnotherapy firmly as a scientific treatment method.

". . . The teaching of any psychotherapeutic method is best achieved by personal observation and practical experience. For this reason, the manner of presentation in these volumes is somewhat unique. A considerable portion of Volume One is devoted to a step-by-step description of the induction process, illustrating various induction methods by excerpts from transcriptions of actual hypnotic sessions. There is a didactic discussion of the principles of psychotherapy, and of the psychopathologic factors in the different disease syndromes.

"Volume Two contains three complete transcribed case histories which enable the reader to follow the various stages in treatment, and to observe the therapeutic management of the patient as if he were personally present at the sessions from the beginning to the end of therapy. In each instance, these illustrate a preceding discussion of the uses and limitations of the chief short-term psychotherapeutic methods.

"Hypnosis adds speed and directness to psychotherapy, but it must not be regarded as a cure-all. A number of emotional problems fail to respond to hypnotherapy and require traditional long-term analytic approaches.

". . . While books such as this work are helpful, and constitute a convenient guide, they merely indicate the lines along which the physician may develop his therapeutic skills. Practical experience, particularly in some psychiatric training center, is indispensable in permitting of a full development and utilization of available therapeutic aptitudes."

In the preface to volume II, the author states: ". . . The present volume describes the joint technics of hypnosis and psychotherapy by presentation of actual case material through complete transcription of a number of treatment sessions. In addition to several briefer examples, three complete psychosomatic cases are included, illustrative of the three main divisions of therapy presented in this volume.

"The conclusions which have been presented in each of the three types of therapy — symptom removal, psychobiologic therapy and psychoanalytic therapy — are based on clinical experience with a fairly wide variety of cases. As more experience is gained in the different treatment methods, however, a modification and revision of these conclusions will undoubtedly be required."

These quotations accurately indicate the contents of this well written, well organized book. There is an excellent bibliography placed at the end of each chapter and a good adequate index. This book is recommended reading for every psychotherapist whether or not he employs hypnosis in his professional work.

Practice of Allergy. By Warren T. Vaughan, M.D. Second edition revised by J. Harvey Black, M.D. Fabrikoid. Price, $15. Pp. 1132, with 333 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

This book by the late W. T. Vaughan is generally considered one of the best textbooks and standard reference books on the subject. In the preface of the second edition, J. Harvey Black expresses the difficulty of carrying on the tradition established by its original author. The reader senses that Vaughan's vast experience and indefatigable search for knowledge on the subject are lacking. This becomes apparent from a cursory glance at the otherwise extensive bibliography, which contains relatively few recent references in spite of the abundance of new material on the subject.

This edition follows the outline of the previous one, the highlights being the chapters on food, fungi and pollen, which are most comprehensive and remarkably well illustrated. The part on pollen especially, written by O. C. Durham, the recognized authority on the subject, is excellent. Such important contributions to allergy as antibiotic therapy or the new theories concerning the allergic background of the collagen diseases are only casually mentioned or omitted entirely. On the psychosomatic aspect of allergic diseases, further elaboration would be desirable. Little is said about complications of asthma and nothing on the subject of the rehabilitation of the asthmatic patient. While there is an adequate chapter by J. B. Howell on local treatment of fungous diseases of the skin, no mention is made of local measures for atopic eczema. In treating hay fever, the most effective means of properly gaging the doses is not stressed; namely, the observation of the degree of local edema from each injection. In coseasonal treatment, few allergists follow the practice of administering 0.3 cc. of epinephrine with the pollen extract. The important subject of urticaria and angioneurotic edema is confined to four pages. More detailed elaboration on the therapeutic management of the individual allergic diseases would have been more useful than a chapter on pharmacology of allergy.

In spite of these minor criticisms, this book remains one of the most valuable textbooks on the subject. The material is most authoritative and instructive. The book is well printed and well indexed. It is indispensable to any one interested in allergic diseases.

Modern Trends in Dermatology. Edited by R. M. B. MacKenna, M.A., M.D., F.R.C.P., Physician in Charge, Dermatological Department, St. Bartholomew's Hospital, London. Cloth. Price, $8.50. Pp. 432, with 32 illustrations. Paul B. Hoeber, Inc., 49 E. 33rd St., New York 16, 1948.

This excellent volume is a collection of eighteen articles on recent advances and knowledge relating to dermatology. The majority of chapters have been written by outstanding specialists in collateral branches of medicine. The wisdom of this choice is evidenced by the ability of these authorities to assess scientifically the value of new discoveries in their special subjects. Although primarily written for the dermatologist, this book also serves to clarify some of the interrelationships between dermatology and internal medicine.

The volume is introduced by a brilliant chapter on the mechanism of research, emphasizing the need for fundamental thinking and creative work in functional fields. How wide is the abyss between the gifted observer of the commonplace and the sterile case reporter of one more unimaginatively studied and unimportant rarity! The chapter on nutrition is written with disarming candor. In it, Marrack states that while the treatment of some diseases of the skin with vitamins may be beneficial in a higher series of cases than can be ascribed to chance, the effect of such treatment is uncertain. He urges a more careful analysis of strictly clinical reports of improvement following vitamin therapy in order to diminish the vast and usually vague therapeusis in this field.

Two thought-provoking sections in this book are new and welcome strangers to the dermatologic literature. The first, in discussing the prevention of cutaneous disease, states that dermatologists must be students of human and social biology inasmuch as the living organism responsible for many diseases of the skin is neither a mite nor a coccus but man, himself. The second unique section embodies programs devised by the British Army to rehabilitate patients suffering from cutaneous disease.

Although the majority of chapters are thorough and adequate, especially those on hormones and the interpretation of statistics, others require modification in order to prevent unnecessary overlapping and the repetition of well known facts. It is always advisable for collaborators to read one another's articles. The chapter on radiation therapy is uncritical and overly optimistic. For example, the author states that roentgen therapy is effective in psoriasis but neglects to add the words "temporarily and cautiously." The section on therapy is only fair. The surveys of physiology and functional pathology review much recent investigative material but are repetitive and could well be combined with the chapter on anatomy. Many of the aforementioned research projects clearly show that human skin differs so profoundly from that of other animals in structure, function and therapeutic response that one can learn about it only from studies on human beings.

In general, the book is a timely and comprehensive study of dermatologic knowledge. It should be of lasting value to dermatologists and senior students of dermatology.

Thérapeutique par la pénicilline. [Le premier Congrès française de la pénicilline,' 1946.] Ministère de la santé publique. Service central de la pharmacie. Paper. Pp. 894, with illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6ᵉ, 1947.

In the United States 21,491 billion units of penicillin were produced during the first three months of 1948. In the same period in 1947, the output was 7,780 billion. This great increase in output reflects two things: first, more and more penicillin is being used by physicians for the treatment of infections and, secondly, it continues to be the most potent chemotherapeutic agent for the treatment of a wide variety of infections.

In April 1946 a congress was held in Paris to discuss the results of the application of penicillin in France. This four day meeting was sponsored by the Minister of Public Health, Dr. Cavaillon, and the various papers presented are now available in this 894 page book. The first part consists of four chapters on general reports of interest to internists, surgeons and their respective specialties. The second part gives the detailed studies of many physicians throughout France in a variety of infections. The third part is a statistical summary of the results. The papers present clearly what can be accomplished with penicillin in relatively low doses. There are a great many well documented case reports. For all physicians interested in the application of penicillin, this monograph can be recommended for purposes of reference and reading.

The 1946 Year Book of Neurology, Psychiatry and Neurosurgery. Neurology. Edited by Hans H. Reese, M.D., Professor of Neurology and Psychiatry, University of Wisconsin Medical School, Madison, and Mabel G. Masten, M.D., Associate Professor of Neuropsychiatry, University of Wisconsin Medical School. Psychiatry. Edited by Nolan D. C. Lewis, M.D., Director, New York State Psychiatric Institute and Hospital, New York. Neurosurgery. Edited by Percival Bailey, M.D., Professor of Neurological Surgery, University of Illinois, Chicago. Fabrikoid. Price, $3.75. Pp. 732, with 103 illustrations. The Year Book Publishers, 304 S. Dearborn St., Chicago 4, 1947.

The 1946 Year Book of Neurology, Psychiatry and Neurosurgery represents a gallant effort to keep abreast of the rapidly mounting volume in these three disciplines. The abstracts have been carefully selected, but the limitations of space precluded the inclusion of a number of important contributions. Of the 709 pages, 292 are devoted to neurology, 247 to psychiatry and the remainder to neurosurgery. Perhaps the allotment of space in the three categories is somewhat disproportionate. At least as much space might have been given to psychiatry as to neurology. The distribution of subjects in the field of psychiatry is rather good—general topics, child psychiatry, schizophrenic reactions and other psychoses, organic reactions, toxic psychoses, psychoneuroses and psychosomatic disorders, military psychiatry and special therapy. Probably the psychoanalysts will feel that psychoanalytic literature has been treated in stepchildish fashion. The references to psychoanalytic literature are few. The Quiz Section, which is an added feature, lends itself more naturally and readily to neurologic and neurosurgical subjects than to psychiatry. In the first two categories, information is often concrete enough to admit of more or less definite questions and answers. While the body of psychiatric information is considerable, it does not lend itself well to streamlined questionnaires, and treatment on this level is not favorable to a rapidly developing discipline.

It would seem desirable to publish two Year Books, one for neurology and neurosurgery, and the other for psychiatry. Among other things, this plan would give psychiatry more much needed space. Furthermore, it would permit more consideration of the psychiatric implications of internal medicine, pediatrics and the other subdivisions of medicine and surgery with which psychiatry now has such an intimate and productive liaison, at least as fruitful as the contacts with neurology and neurosurgery. Despite faults, largely due to trying to encompass the review of three important subjects in too few pages, the Year Book is a meritorious achievement.

Teaching Psychotherapeutic Medicine. Edited by Helen Leland Witmer, Ph.D. An Experimental Course for General Physicians Given by Walter Bauer, M.D., and others. Introductory Chapter by Geddes Smith. Cloth. Price, $3.75. Pp. 464, with 5 illustrations. The Commonwealth Fund, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1947.

This book is a compilation of the recorded verbatim discussions between a group of general practitioners, seven psychiatrists and two internists during a two week course of study. There is, first, a lecture, then actual case presentation followed by an exchange of information based on the personal experience of the authors. These discussions make the book especially valuable to any physician, specialist or general practitioner who encounters these same problems in his daily practice. This is one of the few books on psychosomatic medicine which actually are concerned with the heart of the problem; namely, how to handle a patient with psychogenic complaints. Most of the current publications are so bogged down with confusing terminology, broad generalizations and lengthy verbiage that the average intelligent physician can find little information in them to help him in the actual treatment of the patient. This book will make the physician more secure in the handling of patients with psychogenic complaints.

Exercise During Convalescence: A Manual of Adapted Exercises. By George T. Stafford, Ed.D., Professor of Physical Education, University of Illinois, Urbana, Ill. Cloth. Price, $4. Pp. 281, with 36 illustrations. Drawings by William S. Pusey. A. S. Barnes & Co., Inc., 67 W. 44th St., New York 18, 1947.

This book is written particularly for those engaged in rehabilitation work in the armed services. Physiatrists and physical and corrective therapists will find many helpful suggestions in planning their convalescent programs. The author is well qualified by his many years of experience in physical education. The book contains thirteen chapters. Dr. Stafford states that all programs, such as he outlines, must be carefully supervised by a physician and by one well trained in physical medicine. Physical educators with an excellent knowledge of kinesiology are qualified to give a general exercise program. Caution, however, must be used with regard to general and especially specific exercise programs in civilian hospitals, which do not have many strong, young men patients who can take a convalescent program as outlined in the book. Many are either too young or too old, and many have conditions which require an accurate program of muscle reeducation. The average physical educator usually has had no specific training in muscle reeducation. Corrective gymnastics are often thought to include this, but they actually do not, since corrective gymnastic exercises are meant to cover large muscle groups usually and not to require specific attention to true muscle reeducation or to the orientation of specific muscles. Therefore it is inadvisable to have physical educators treat the sick and handicapped except to give exercises for the uninvolved parts or conditioning exercises to nearly normal patients. With these cautions in mind, this book offers real help toward hastening the patient's recovery by exercise during convalescence.

Operative Oral Surgery. By Leo Winter, D.D.S., M.D., F.A.C.D., Professor of Oral Surgery, New York University, New York. Third edition. Cloth. Price, $12.50. Pp. 1167, with 1240 illustrations. The C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

This is a good textbook for students. The diagrams and drawings on the chapter of local anesthesia are most explicit and instructive. Under general anesthesia, the various drugs, technics, difficulties in their use and, above all, the value of preanesthetic medication are well described. The section on chemotherapy brings the student up to date. The chapter on exodontia is profusely and well illustrated, but the author has a tendency to refer wrongly to all unerupted teeth as impacted teeth. Surgical technic of the removal of teeth is described and illustrated in detail.

A large section of this book is devoted to tumors. The author includes and describes the operation known as apicectomy under "cysts of the jaws." This procedure is done only under certain conditions such as when there are nonvital teeth with periapical infection. Photographs, diagrams, and roentgenograms are numerous and enhance the excellent description in the text. In the discussion of adamantinomas, it would probably be better from a teaching standpoint to discuss the etiology before the symptomology. There are two schools of thought on the operation referred to as alveolectomy; namely, that it should be immediate and that it should be delayed. The latter is not discussed at all. The author suggests consultation with the rhinologist in fractures of the maxilla where there is nasal and antral involvement. The trend is to refer such cases to men capable of handling extensive fractures of the face rather than to divide responsibility unnecesarily.

The first Gilmer method of intermaxillary wiring for mandibular fractures is no longer used, except possibly as a temporary emergency measure, to be substituted later. In mandibular fractures, the author has a tendency to advise general anesthesia for reduction. Most men in this work use local anesthesia or sedatives alone. The use of general anesthesia is the exception rather than the rule. For clarity and continuity, the immediate treatment of the injured patient should be discussed before the mechanical treatment of the fractured jaws rather than after.

The chapter on diseases and disturbances of the temporal mandibular joint is a most welcome addition to the literature.

Laboratory Technique in Biology and Medicine. By E. V. Cowdry, Professor of Anatomy, Washington University, St. Louis. Second edition. Fabrikoid. Price, $4. Pp. 269. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

The title of this book, which has been changed from "Microscopic Technique" in the first edition, is misleading, for the book still deals almost entirely with microscopic technics and expositions of microscopic findings. After brief chapters on choice of methods of biologic study and on standardization of stains, the book is essentially an encyclopedic dictionary of biologic terms and technics. The subjects are arranged in alphabetical order and the expositions vary in length from 1 line to 11 columns. Many of the long articles are by guest authors,. as for example "Oxidation-Reduction Potential," by C. Carruthers, and "Quartz Rod Technique," by M. H. Knisely. The chief value of the book is as an introductory reference to laboratory phases of biology. It will be of most value to the young research worker in any field of histology. To the experienced histologist, descriptions of the technics, though brief, have enough detailed information to serve as a good laboratory reference book.

Clinical Endocrinology and Constitutional Medicine. By A. P. Cawadias, O.B.E., M.D., F.R.C.P., Endocrinologist to the Order of St. John Clinic, London. Fabrikoid. Price, 42s. Pp. 368, with illustrations. Frederick Muller, Ltd., 29 Great James St., London, W. C. 1, 1947.

In the preface the author regrets that the late Sir Thomas Lewis "unfortunately over-emphasized the physiopathological chapter of diseases and under-rated the great importance of clinical observation." He then presents over 300 pages of unscientific nonsense and modestly (sic) concludes "I have developed the modern constitutional point of view on medicine" (page 359). In the treatment of goiter he says, "I prefer the homeopathic dilution (6 times) as the dangers of aggravation through iodine, and of production of a toxic goitre, are very real" (page 82). American physicians will be surprised to find that in the treatment of Graves' disease "protein restriction is indicated because proteins raise metabolism and tire the liver" (page 99). The author has seen good results from "galvanisation or galvano-faradisation of the thyroid." In the treatment of myxedema he advises, as an adjuvant to thyroid, the use of sulfur. On page 100 he states, "It is a powerful oxidiser, and can be used either in colloidal form, as an absorbable organic preparation, or in homeopathic form."

In regard to the treatment of diabetes he writes, "Spa treatment is of the greatest importance and except in very severe cases should always be prescribed. Choice of spa is based on the special features of various mineral waters. According to individual features, Vichy, Vittel, La Bourboule, Harragate or Bath is selected. High altitude health resorts, particularly those of the Engadine, often prove far more beneficial than spas."

The author makes the statement that, in the treatment of diabetic acidosis, "An enema or aperient is necessary for elimination of poisons". (page 314).

Headings which are intriguing are used, such as The Postpuberal Hypotestosteronic Eunuchoid, Cerebropituitary Hyperoestrinic Metrorrhagia, Hypotestosteronic Morpho-Psychological Androgynoidism, Cerebro-Pancreatic Hyperinsulinic Hypoglycaemia.

This is just about the worst book on endocrinology the reviewer has ever seen. It is incredible that, when the school children in England are deprived of textbooks because of a shortage of paper, so much should have been wasted in this book. Few American physicians will wish to aid in the depletion of England's supply of paper by purchasing this book. Most will continue to be grateful to Sir Thomas Lewis for his contributions to science and medicine.

Pharmacology and Therapeutics in Nursing. By Marion Sylvester Dooley, A.B., M.D., and Josephine Rappaport, R.N., B.S., Assistant Chief, Nursing Education, Veterans Administration Hospital, Alexandria, Louisiana. Cloth. Price, $3.75. Pp. 444, with 26 illustrations. McGraw-Hill Book Co., Inc., 330 W. 42nd St., New York 18, 1948.

This new textbook has an entirely new approach to the problem and should be useful for the nurse. The nursing care is emphasized. It is increasingly important for the nurse to be familiar with the drugs, particularly the new ones. As the authors state, "by concentrating the discussion on standard drugs and using the metric system throughout, it saves priceless hours."

There are only a few criticisms. On page 91 under the anticonvulsants no mention is made of trimethadione ("tridione"). On page 159 "mecholyl chloride" and "mecholyl bromide," which has a much wider use, are not mentioned at all. On page 162 appears the statement, "taking it to 'reduce' is also a dangerous delusion." This, of course, is not true. There have been many reports of the usefulness of amphetamine sulfate ("benzedrine sulfate") in the diet program for weight reduction. On page 318 the use of gentian violet is mentioned for the treatment of pinworms. However, it is important to mention that treatment with gentian violet must be continued for three alternate weeks in order to be effective. The greatest number of failures is due to the fact that gentian violet is not given in a large enough dose or for a long enough period of time.

Physical Education: Interpretations and Objectives. By Jay B. Nash, Ph.D., Chairman of the Department of Physical Education and Health, School of Education, New York University, New York. Cloth. Price, $3. Pp. 288, with illustrations. A. S. Barnes & Co., Inc., 67 W. 44th St., New York 18, 1948.

In this little volume the author attempts "to investigate the place of education in a democracy; to indicate the specific contributions of physical education to general educational objectives; to indicate the relationships between physical education as a teaching subject and democratic outcomes in terms of health, recreation and citizenship."

Part I does a good job of defining physical education and showing its important place in the educative process. It is marred by a minor inaccuracy on page 42, where the author states that the one crop pattern of farming through diminishing the mineral resources of the soil is "a predisposing factor of rickets for millions of people."

Part III is introduced by a baffling figure showing the four level development in education in man. Over the figure is the cryptic title "Organismic Whole Gestalt of Emergents." On the next page the author falls into the error of defining immunity only in the limited terms of phagocyte proliferation. But in spite of this inauspicious beginning, part III is perhaps the most valuable part of the book because of its elucidation of organic, neuromuscular, interpretive (cortical) and emotional development.

In part IV, the author discusses recreation, health and character as objectives of physical education; it is a pleasure to note his broadmindedness in such statements as the following: "Physical education has had no monopoly on the setting up of or the contributions to recreational standards. This has been the responsibility of all education and of the total community. A special tribute should be paid to science, vocational education, music and the languages." "Physical education has no monopoly on contributions to the health of the human organism. As a matter of fact, in comparison with all the other educational and community factors, its contributions are relatively small. The very name, Department of Health and Physical Education, carries some unfortunate connotations. One of them is that health and physical education are synonymous or, even worse.

that physical education departments should take over the responsibility for the health of the school-age child. Both of these ideas are very unfortunate."

Though this volume is written primarily for use as a text for students majoring in physical education, it should hold interest for school administrators, school physicians, health educators, recreation leaders and parents.

Myotonia: Thomsen's Disease (Myotonia Congenita), Paramyotonia, and Dystrophia Myotonica: A Clinical and Heredobiologic Investigation. By Eivind Thomasen. Translated from Danish by Finn Brink Carlsen. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig.at forsvares for den medicinske Doktorgrad, København. Paper. Pp. 251, with illustrations. Universitetsforlaget i Aarhus, Aarhus, Denmark, 1948.

This excellent review and report of new cases of myotonia comes from the hospitals and scientific departments associated with the University of Copenhagen and from the Institute for Human Genetics in Denmark. The translation from Danish into English, although a little stilted, is so good that the author's meaning is seldom unclear. The various forms of myotonia are fully delineated, the text being supplemented by pertinent illustrations, an adequate bibliography and case reports of twenty families. The book only lacks an index to make it a completely useful monograph on two syndromes of muscular disability. To Thomsen's original concept of myotonia congenita, first described from his own symptoms in 1876, has been added a subvariety, paramyotonia. Dystrophia myotonica, which the author feels is a different disease, also has myotonia as one of its symptoms. Myotonia acquisita, a nonhereditary type of myotonia, does not, in Thomasen's opinion, have sufficient basis for differentiation as a special group. Myotonia congenita, on the other hand, shows dominant heredity, with varying manifestations. The author gives a brief biography of Dr. Thomsen and traces additional cases in his family from persons now living in Denmark. Myotonia disappears with heavy doses of quinine, a drug of some use in the treatment of Thomsen's disease, but less valuable in cases of dystrophia myotonica. Thomasen found that most patients with myotonia were made worse by cold, fatigue, menstruation and pregnancy. Fright may bring on an acute attack. The disease tends to become less burdensome in old age. These conclusions, and others of equal value, carefully compiled by the author, give the book an outstanding position in the literature of muscular diseases.

Intracranial Tumors. By Percival Bailey, Professor of Neurology and Neurological Surgery, University of Illinois, Chicago. Second edition. Cloth. Price, $10.50. Pp. 478, with 171 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois, 1948.

This admirable book has evidently been very popular, for a second edition has had to be brought out. In the preface to this edition, the author states that "errors have been corrected and recent advances in our knowledge inserted," but this reviewer, with the first edition alongside of the second, has found few changes.

The two important advances in neurologic surgical diagnosis that have been made since the first edition appeared are angiography and electroencephalography. On the first of these, the author comments briefly (page 395); he expresses the hope of being able by this method to detect glioblastomas and other types of tumors before operation. About electroencephalography, however, he does not comment at all; at least, this reviewer has been unable to find a reference either in the text or in the index, though there is one reference to the subject (no. 226) in the bibliography. Yet it would have been of real interest to have had the author's opinion about this method of examination and his estimate of its value.

There are a few inconsistencies that are rather striking. In his preface, the author says that localization of tumors has been solved by the introduction of ventriculography; yet on page 395 he states that he makes use of it in only 15 per cent of his cases. This is not in accord with usage now customary in most neurosurgical clinics. The difficulty the author describes in diagnosing tumors of the third ventricle might be somewhat obviated if air were injected in one side only, and then roentgenograms taken before air is injected on the second side.

Because of the author's objection to glazed paper, it was not possible, in either edition, to reproduce roentgenograms. Therefore drawings of roentgenograms were made which, to many readers, are unsatisfactory. For the same reason, drawings of patients were used instead of much more satisfactory photographs. Hence, in the new edition, both reviewer and reader will undoubtedly welcome the inclusion of an atlas of sixteen roentgenograms which are well reproduced. If only there had been more!

The criticisms expressed in this brief review in no way detract from the great value and importance of this work. The author is one of the leading authorities on the pathology of brain tumors, and the subject is approached primarily from that angle. His views throughout are sound and based on vast experience. This book should be in the library of every neurologic surgeon. Furthermore, it is so clear and so readable that all medical students would do well to study it.

The Engaged Couple Has a Right to Know: A Modern Guide to Happy Marriage. By Abner I. Weisman, M.D., Assistant Visiting Gynecologist and Obstetrician, Metropolitan Hospital, New York. Foreword by Dr. Abraham Stone. Cloth. Price, $3. Pp. 256, with 14 illustrations. Renbayle House, 1165 Broadway, New York 1, 1948.

The past few years have brought out many much needed books for engaged couples and those needing help in marriage adjustment. This book deserves to be high on the list of recommended books in this field. It is most inclusive without being too lengthy. It touches on marriage historically, as well as giving it place in present day society. It discusses readiness for marriage and how to select a mate. It takes up health and physiology and the role of sexuality in a frank and capable manner. It also goes into the matter of blood incompatibility and sterility, a field in which the author is already an authority. It discusses the honeymoon and sexual adjustment and even includes the advent of the first baby, as well as the various facets of planned parenthood. There is a forward by Dr. Abraham Stone and a fairly lengthy list of suggested reading for young persons contemplating marriage. The author is a gynecologist who has already written for the medical profession and the laiety. It is a welcome phenomenon to see a book so sensitive to the emotional and social problems within medical practice come from one within a speciality other than psychiatry.

Die Bildung des Arztes: .Ein Beitrag zur Bildung des Menschen überhaupt. Von Curt Oehme. Paper. Pp. 39. F. H. Kerle Verlag, Theaterstrasse 18, Heidelberg, 17a, 1948.

This is an interesting monograph comprising a series of lectures presented at the University of Heidelberg on the problems of general and professional education facing Germany today.

The roots of the present depression in medical education can be traced as far back as the first World War, as shown by the comparatively few contributions to medical knowledge published in German periodicals since that time.

Social economic conditions, the Nazi-autocratic restriction of scientific interchange with other countries, have interfered with medical progress as compared with England and America. Racial prejudice and war psychoses have been a further factor, and the story of the Nuremberg trials distinctly reflected the low plane to which the greatness of German medicine had fallen.

The present chaotic state of German medical education is ascribed to four causes: (1) the lowering of premedical educational standards, the mass admission of large numbers of students poorly prepared for the study of medicine and inadequate teaching facilities in the several university medical schools; (2) an attitude of arrogant self satisfaction with the existing educational system; (3) loss to medical faculties of the great leaders of a former day; replacements can only be made from younger physicians inadequately prepared for medical teaching; (4) teaching at the bedside and careful laboratory training are practically nonexistent, while the spirit of research is hardly evident anywhere.

The author maintains that a revival of medical education in Germany implies a complete revision of the entire educational system, and above all a reawakening of the spirit and soul of medicine. A generation will pass before the results of the teaching of a sound philosophy of living will be evident. The author makes the plea for a more humanistic approach to the study of medicine, coupled with a more complete preparation for the study of the basic and clinical medical sciences with a keen appreciation of their spiritual and cultural values in the art and practice of medicine.

Such, according to the author, is the challenge that confronts medical education in Germany today.

Public Health Administration in the United States. By Wilson G. Smillie, A.B., M.D., Dr.P.H., Professor of Public Health and Preventive Medicine, Cornell University Medical College, New York. Third edition. Cloth. Price, $6.50 Pp. 637, with 43 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1947.

This splendid textbook, first printed in 1935, is now in the third edition and has been thoroughly revised. It is well indexed, nicely arranged, rather well illustrated, particularly with graphs, and in general gives an attractive appearance. Part I has to do with organizations in the United States. Part II has for its subject "The Administrative Control of Cmmunicable Diseases"; part III, "Basic Activities of a Health Organization," and part IV, "Organization of Public Health Programs."

The book is subdivided in such a way that it will be easily used as a textbook and has evidently been arranged with that in mind. Particularly suitable would be the use of this book by junior or senior medical students. It is well documented at the end of the chapters.

Dr. Smillie has done a notable work in preparing this book and keeping it up to date. It can be recommended without reservation.

A Handbook for Dissectors. By J. C. Boileau Grant, Professor and Director of the Department of Anatomy, University of Toronto, Toronto, and H. A. Cates, Professor of Anatomy, University of Toronto. Third edition. Cloth. Price, $3. Pp. 415, with 19 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

This excellent little book is of especial value to medical students at this time. The third edition is the product not only of many years sound teaching, but also of eight years' experience with the earlier editions. The first edition referred to the authors' textbook only; this one does not refer to any single textbook but can be used with equal convenience with any or all of them. Its outlook is clinical—preparation for medicine and surgery. Sound knowledge of gross human anatomy is obviously a basic essential of such preparation. Dissection is rightfully required by all the state laws. But biochemistry, bacteriology, pharmacology, etc., are also fundamental and must have places in the preclinical medical curriculum. The time available for dissection is reduced, and therefore cannot be wasted but must be spent to the greatest advantage. On this consideration the Canadian book is admirable. On completing one careful dissection with its guidance, medical students can go on with the medical curriculum. But most medical students are also students of general biology and specialists in some field. They cannot be content with the minimum study of gross human anatomy. They will return to it many times, often with further dissection.

Your Skin and Its Care. By Howard T. Behrman, M.D., and Oscar L. Levin, M.D. Cloth. Price, $2.50. Pp. 255, with illustrations. Emerson Books, Inc., 251 W. 19th St., New York 11, 1948.

This book is intended for the lay reader, although it contains information which is presented in such a way that it makes interesting reading for others who wish orientation concerning knowledge of the skin. Fourteen chapters provide discussions on the structure of the skin and its function, the relation of health to the skin, care of the face, quackery, diseases of the skin, care of the hair and other problems of similar nature. The book is not too technical for those who have a genuine interest in their skin problems, although of course it is not intended as a textbook for medical students or others who have need for specialized training. It is the type of book to which the physician can refer his patients who want more information than can be obtained during the average consultation session.

Diseases of the Eye. By Sir John Herbert Parsons, C.B.E., D.Sc., F.R.C.S., Consulting Ophthalmic Surgeon, University College Hospital, London, and Sir Stewart Duke-Elder, K.C.V.O., M.A., D.Sc., Surgeon Oculist to the King. Eleventh edition. Fabrikoid. Price, $7. Pp. 732, with 389 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

The eleventh edition of this popular short textbook has been revised to include therapy with penicillin and sulfonamide drugs and short descriptions of toxoplasmosis and brucellosis. There are included chapters on causes and prevention of blindness, hygiene of vision, outline for complete examination of the eyes and therapeutic notes giving strength and dosage of drugs used in ophthalmology. The final 14 pages give the visual requirements of Great Britain for the army, navy, air forces, civil aviation, merchant marine, railroad workers, civil employees, police force and drivers' license.

The book is an adequate short textbook in ophthalmology for students and general practitioners.

Sport und Kreislauf. Sammlung der Referate gehalten am IV. Sportärztlichen Zentralkurs 1946 in Lausanne. Herausgegeben durch den Schweizerischen Landesverband für Leibesübungen und die Verbindung der Schweizer Ärtze. Mit Unterstützung der Firma Dr. A. Wander A. G., Bern. Paper. Price, 12.80 Swiss francs. Pp. 154, with 21 illustrations. Hans Huber, Marktgasse 9, Bern, 16, 1947.

This little volume is a compilation of the reports made on the heart and circulation at the 1946 Sports Physicians' Conference held at Lausanne, Switzerland. Previous to World War II, a good deal was heard about the European sports physicians and the interest abroad in study and research on the physiologic results of sports activity. Evidently in postwar years there is renewed interest among physicians in this subject. Included in the symposium are papers on functions of the heart and circulation in reference to participation in sports, cardiologic considerations in sports medicine, electrocardiographic changes in connection with continued physical effort, ergometric and spirometric measurement of reaction to exercise, suggestions on the examination of school children and a supplement on research in sports medicine.

The Treatment of Impotence with Special Reference to Mechanotherapy. By Joseph Loewenstein, M. D. Foreword by Eric B. Strauss, D.M., F.R.C.P., Physician for Psychological Medicine, St. Bartholomew's Hospital, London. Cloth. Price, 6s. Pp. 49, with 4 illustrations. Hamish Hamilton, Ltd., 90 Great Russell St., London, W.C.1, 1947.

This short monograph deals primarily with mechanotherapy in the treatment of impotence. The author gives a history of the various apparatuses that have been used in the treatment of impotence, and then describes in detail a gadget called the "coitus training apparatus." Then follows a discussion of indications and technic of its use. Eleven case reports of impotence treated by this method combined with psychotherapy are given. It is difficult to evaluate this method of treatment. Apparently, from the evidence presented, the gadget described by the author has a place in the treatment of some forms of impotence. This monograph will be of greatest interest to those who specialize in sex disorders.

An Index of Modern Remedies. By William Mair, F.R.S.E., F.C.S., M.P.S. For the Medical and Pharmaceutical Professions Only. Fourth series. Paper. Price, 3s. Pp. 68. The Scottish Chemist, 240 Albert Drive, Pollokshields, Glasgow, S.1, 1948.

This brief index of remedies is concerned primarily with the agents that are available in the British Isles, and for this reason the booklet will provide a source of information to those that are interested in the nomenclature and composition of British remedies. It is not, of course, a therapeutic guide. The booklet will be of interest primarily to the teacher, librarian and those who occasionally have reason to interpret prescriptions from Great Britain.

Tabulae biologicae. Editores: G. Backman, et al. Vol. XXII Pars I.: Oculus. Editores: K. Steindorff, E. P. Fischer, J. S. Friedenwald et Arnold Sorsby. Paper. Pp. 408, with illustrations. Uitgeverij Dr. W. Junk, N. Z. Voorburgwal 64, Amsterdam (C), 1947.

This paper-covered book, which is part I of volume XXII, is concerned with the eye. In part it is a tribute to Kurt Steindorff, who was one of the early students of the eye. Chapter by chapter pertinent information concerning this organ is presented, so that those with various interests—biologist, chemist or surgeon—will find interesting data.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

NITRITOID REACTION

To the Editor:—Nitritoid reactions are not supposed to occur with oxophenarsine hydrochloride. Please give an opinion on the following reaction and suggestions for future management. The patient is a white woman aged 19 years. Except for secondary syphilis when the patient was first seen, physical examination was completely negative. History of exposure or contact is lacking, so that the date of the primary lesion is unknown. The treatment followed was that recommended by the Cooperative Clinical Group for early syphilis. During the initial part of this schedule, she also received 8,500,000 units of penicillin. Until two weeks before I first saw her reactions were absent except for occasional moderately severe nausea beginning an hour or two after the administration of the oxophenarsine. These cleared completely on the following morning. Reactions did not occur during the bismuth phase. Then, within five minutes of an injection of freshly prepared oxophenarsine, her face became slightly flushed, she complained of lightheadedness, appeared anxious and suddenly fainted. The pulse was extremely weak, and respiration was shallow. She responded to epinephrine, but was weak and had nausea with retching for a half hour after she recovered from the faint. Nausea persisted for several hours, until she fell asleep for the night. This reaction occurred on the fourth injection in the second oxophenarsine series. To be certain that it was not partly of psychic origin, I gave her an injection of sterile water the next time and reaction did not occur. She is now receiving bismuth compound again and there have been no more reactions. Is it advisable to continue the oxophenarsine when it is time to start it again and have her take ephedrine the day before and after the injection, or use some epinephrine preceding the injection? Is it better to use a different arsenical, or eliminate use of arsenicals entirely?

M.D., Pennsylvania.

Answer.—The question whether this 19 year old female patient with secondary syphilis requires any therapy with arsenic or bismuth compounds depends on when she received the 8,500,000 units of penicillin and how it was given. If this amount of penicillin was administered early in the patient's treatment, and given every two or three hours day and night in aqueous solution within a period of four to fifteen days, or if, alternatively, it was given by daily intramuscular injections of penicillin in an absorption-delaying medium, such as peanut oil-beeswax or procaine penicillin, over a period of ten days or more, little if anything is to be gained by giving her arsenic and bismuth compounds. The chance of improving on the results of this amount of penicillin alone are relatively small and the risks of treatment greatly increased.

Eight and one half million units of penicillin given for secondary syphilis will provide a 10 to 20 per cent failure rate at the end of eighteen to twenty-four months. Conversely, it will provide an 80 to 90 per cent chance of "cure" without the addition of arsenical therapy. The consensus, as expressed in the report of the Syphilis Study Section to the Council on Pharmacy and Chemistry, "Penicillin in the Treatment of Syphilis" (J. A. M. A. **136**:873 [Mar. 27] 1948), is that penicillin should be used alone as an initial course of treatment for early syphilis. Arsenic and bismuth compounds, if employed at all, should only be used as retreatment combined with penicillin in the event of failure of the first course of treatment.

It is suggested that in this patient treatment now be stopped and that she be followed at monthly intervals with physical and quantitatively titered serologic recheck examinations. If her progress is satisfactory at the end of one year, these recheck examinations may be carried out every three months during the second year and every six months thereafter. The patient's spinal fluid should be tested about six months after the initiation of treatment and again at the end of the second year of observation.

Nitritoid reactions do occur from oxyphenarsine hydrochloride ("mapharsen"), though they are much less frequent than after the arsphenamine series of drugs. If it becomes necessary to use arsenic in this patient again, oxophenarsine should be cautiously employed, beginning with small doses, e. g., 10 mg., and gradually increasing.

ADOPTION

To the Editor:—A couple has made application to a welfare agency to adopt a child. The welfare worker asked them how they would feel about adopting a child under the following conditions. The father and the mother of the child are university graduates. The father is known to have had a positive Wassermann reaction. The mother's Wassermann reaction has always been negative. Examination of cord blood at the time of the birth of the child showed positive reaction. However, repeated Wassermann tests on the child and mother after delivery have elicited negative reactions. No history as to kind or type of treatment either of father or mother was obtainable. This couple wants to know whether there is any chance of the development of congenital syphilis in the child or whether it is likely that any congenital deformity or weakness could show up from this condition in later life. I have been asked to give an opinion on this matter before they consent to adopt the child.

M.D., Arizona.

Answer.—It is difficult to give a specific answer to the inquiry because the age of the child to be adopted is not given. The fact that examination of cord blood at the time of the child's birth gave positive results does not indicate that the child does have or will have congenital syphilis, because that serologic test is of the mother and not of the child. The question whether or not congenital syphilis will develop depends not on whether the antigen went over into its blood stream, but on whether the Treponema pallidum did. If the antigen alone, and not the T. pallidum, went through to the child's blood, the reaction to the child's serologic test usually will become negative within a period of approximately four months. Accordingly if the child to be adopted is more than 6 months old, if it has had repeated serologic tests with negative results since a month or so after birth, and if the child manifests no signs of congenital syphilis, the probabilities are that evidence of the disease will never develop. It would be advisable, however, to have the child examined by a pediatrician interested in syphilis or a syphilologist before approval is given to adoption of the child.

SYPHILIS IN PREGNANCY

To the Editor:—A woman is now pregnant for the fourth time in eleven years. About three years prior to her first pregnancy, a 4 plus Wassermann reaction was obtained in the course of a routine examination. The only history obtainable relative to syphilis was that old medical records revealed that her mother had died of aortic heart disease and had also had a 4 plus Wassermann reaction. Older and younger siblings were examined repeatedly and found to have negative serologic reactions. While this patient did not show stigmas of syphilis, and did not give any history suggestive of primary or secondary lesions, she was given a full course of treatment with oxophenarsen hydrochloride and bismuth compound. She was again treated similarly during each of her previous pregnancies, giving birth to normal children without physical or serologic evidence of syphilis. In spite of the extensive treatment and child bearing, the patient continues to have a 4 plus serologic reaction. Should she be treated again during this pregnancy? If she is to be treated, can penicillin be substituted for arsenicals, which the patient dreads because of the unpleasant minor side reactions which have accompanied these injections? If penicillin is to be used, what dosage do you recommend for ambulatory treatment with penicillin in oil and wax or the newer procaine penicillin preparations? What is the optimum time to treat the patient?

Fred S. Taber, M.D., New Brunswick, N. J.

Answer.—A woman with congenital syphilis runs virtually no risk of passing the disease to her unborn child, even though untreated. Since the evidence of congenital infection of the mother in the present instance is inconclusive, however, it must be assumed that her disease is acquired. The syphilis status of the woman's husband is not mentioned. If he has not been examined it might be worth while to do so, since a positive blood serologic reaction or other evidence of the disease would make the possibility of an acquired infection in this woman more likely.

A woman who has had adequate treatment with arsenical and bismuth compound for syphilis and who has responded normally runs virtually no risk of giving birth to a diseased infant, even though untreated during her pregnancy. Cole and the cooperative clinical group in their article, "Syphilis in Pregnancy" (*Ven. Dis. Inf.* **15**:83 [March] 1934) found that among 52 women considered "cured" there had been no evidence of a syphilitic child's having resulted from pregnancies up to fifteen years after infection. The usual advice, however, was to treat in each subsequent pregnancy because of the difficulty of determining "cure." When the disease is of long standing and normal children have resulted as a result of previous therapy the possibility of infection of the fetus becomes even less. Only occasionally does an infected fetus result when the disease in the mother is more than ten years old.

The one disconcerting point in the present case is that the expectant mother is seropositive. Nothing is said of study of the spinal fluid. If this has not been performed it should be done (cell count, total protein, serologic test for syphilis and colloidal test). A good time to carry this out would be during the hospitalization immediately after delivery. A seropositive mother is more apt to have some remaining activity of her infection than a seronegative one, and the risk of an infected fetus if untreated is appreciably greater.

Since penicillin therapy entails so little likelihood of reaction, is so effective in preventing congenital syphilis and is so easily given over a relatively short period, it would probably be wisest to treat such a patient with this drug even though the risk of infection of the fetus without treatment is small. Treatment with penicillin may be given at any time in the pregnancy, preferably before the sixteenth week, but it is effective even in the last month. Six hundred thousand units of penicillin in oil and wax, and presumably similar dosage of procaine penicillin, given once daily intramuscularly for eight days for a total dose of 4,800,000 units, is sufficient. Some workers prefer larger total dose, for example 6,000,000 units in ten days or even more than this, but evidence is lacking that this is necessary to protect the fetus. Only one course need be used and no adjunct chemotherapy with heavy metal compound is indicated. Results of such therapy are described in "Treatment of the Syphilitic Pregnant Woman with Penicillin in Oil Beeswax: A Comparison with Results Obtained Using Aqueous Sodium Penicillin" by N. R. Ingraham Jr., E. K. Rose, H. Beerman and others (*J. Ven. Dis. Inform.* **28**:155 [Aug.] 1947).

It is customary after such treatment to perform a quantitative titered serologic test for syphilis once monthly until term to determine the serologic response and to watch for evidence of serologic relapse. In a seroresistant case such as has been described, however, serologic response to penicillin therapy, other than the fluctuations which normally occur in repeated studies of seroresistant cases, is not to be expected. Treatment, therefore, must be empiric, based on experience with other patients, and serologic follow-up, while of academic interest, will not form a real guide as to the future handling of the mother. It is well to bear in mind that if the mother is seropositive at delivery the infant may also be seropositive though not syphilitic. The serologic follow-up of such an infant is described in any of the recently published standard texts for syphilis.

ERYTHROBLASTOSIS

To the Editor:—A 36 year old white woman is Rh negative and slightly less than two months pregnant. Her husband is homozygous Rh positive. They have 3 living children, the youngest being 10 months of age and the only one of twins born of the last pregnancy to survive. The other twin died soon after receiving 60 cc. of Rh-positive blood when 2 days old. The living twin withstood the same type of transfusion although she did have an epistaxis. The antibody titration, post partum, was 1/32, and a recent test showed the same concentration of antibodies. Since the father is homozygous positive this present pregnancy is certain to result in an Rh-positive baby and therefore a recurrence of erythroblastosis. Are these circumstances a justifiable reason for a therapeutic abortion? If not, is there any method of preventing the development of further antibodies in the mother to endanger the baby? Would induction of labor, or cesarean section, before term increase the chances of the baby? My present plans are to terminate the pregnancy about two weeks before term by induction of labor or cesarean section, depending on the condition of the cervix at that time, and give the baby an exsanguination transfusion of 350 cc. of Rh-negative blood devoid of antibodies through the umbilical vein. Will you please offer any further suggestions or criticisms?

T. A. Strang, M.D., Long Beach, Calif.

Answer.—The query does not furnish information on several points which could help in formulating a more complete answer: 1. What manifestations of fetal erythroblastosis were present in the deceased twin? In the surviving twin? 2. The reference to the antibodies does not state what type of Rh antibody was present. Recent studies' have shown that blocking antibodies have a more ominous prognostic significance than agglutinins. On the basis of the information contained in the query the following answer is offered.

There is no justifiable reason for a therapeutic abortion. Modern methods of treatment, especially replacement transfusion, offer an excellent outlook for saving the majority of infants with fetal erythroblastosis, except those with universal fetal hydrops.

Methods are not available at present to prevent development of further antibodies in the mother.

Opinions of experts are divided on the question of advisability of terminating pregnancy by inducing labor or by cesarian section. It may be that further experience with replacement transfusions will encourage such procedure.

The plan offered in the query is reasonable, but it may be still better to test for Rh antibodies (agglutinins, conglutinins and blocking antibodies) at frequent intervals during pregnancy. Observation of the curve of the various antibodies may be helpful in anticipating the degree of dosage to the baby, and it may help in selecting the time for the operation.

The replacement transfusion should be given only if there are indications for it: evidence of disease, or Rh-positive blood in the newborn infant. The latter must be expected in view of the fact that the father is homozygous Rh positive. In spite of that expectation the baby's blood should be Rh tested immediately after birth.

It is probably better to give no less than 500 cc. as replacement transfusion and to withdraw a similar amount minus about 10 cc. per pound of the infant's weight.

IMMUNIZATION AND LEUKEMIA

To the Editor:—A recent scare has come about in this region about a possible relation between immunizing doses of diphtheria, pertussis and tetanus toxoids and leukemia, especially in children of school age. It there has been anything in the literature I have missed it. At least one nearby physician, I understand, has stopped administering such toxoids, and the rumor has reach such proportion that I would appreciate an authoritative statement.

M.D., Minnesota.

Answer.—Evidence is not available of any relation between diphtheria, pertussis and tetanus immunizing agents and leukemia. Immunization procedures might be instituted against the diseases mentioned, and some time later the discovery made that the child had a preexisting blood dyscrasia. However, Byers and Moll (*Pediat.* **1**:437 [April] 1948) have reported instances of encephalitis following pertussis vaccine injections. Toomey discussed the latter subject at the recent meeting of the American Medical Association June 23, 1948. Except on rare occasions, such as exposure to smallpox, inoculations for the purpose of active immunization are, as a rule, better postponed if the subject is not in good health.

BLEEDING GUMS

To the Editor:—What is recent opinion on causes and treatment of pyorrhea? A married woman aged 36, otherwise in excellent health, has had slightly bleeding gums for years. She has been informed that there is deep pocket formation and loss of alveolar bone around all her teeth, probably due to pyorrhea. She has taken excellent care of her teeth, and had a well balanced diet, including plenty of milk, fresh fruits and vegetables. Basal metabolism and blood chemistry tests are normal. She does have some malocclusion. Periodontists advise the extraction of the most severely involved teeth (though they differ as to how many have to be removed) and claim that they can treat the remaining teeth and arrest the pyorrhea and thus the alveolar destruction. Other dentists are more skeptical of the outcome of periodontal treatment. The patient is particularly concerned about the cause of the gum disturbance because her daugter, aged 9, who has been carefully watched as to mouth hygiene, diet and vitamin intake, has recently shown evidence of bleeding gums. Is such a tendency inherited? Both mother and child have always been underweight.

M.D., New York.

Answer.—The causes of periodontal lesions may be classified for the most part in three categories; i. e., (1) dysfunctional, (2) irritative and (3) systemic or idiopathic, with the possibility of any combination of them. Under these headings may be grouped many individual factors, the principal half dozen of which, in order of importance, are traumatogenic occlusion, poor hygiene, calculus, dietary deficiency, poor restorative dentistry and systemic causation.

On the accurate diagnosis of the etiologic factor or factors will depend the rationale of successful therapy. Starting with the three categories, all the teeth and their supporting structures must be placed in a state of equilibrium in which no tooth or its peridontium is subjected to stresses beyond its physiologic limits during normal masticatory functions. In this regard, the eradication of traumatogenic occlusion is of prime importance. In dealing with the second category, a program must be carried out to bring about the remission of all agencies contributing to inflammatory processes. The third and final category with systemic disturbances includes those conditions which might adversely alter the body metabolism. Failure to recognize some one active causative process may be sufficient to retard or completely forestall a satisfactory prognosis.

The brief history of the case mentioned does not permit a specific answer. It would suggest that the active causes may be both dysfunctional and inflammatory because of the known malocclusion and gingival hemorrhage. The normal basal metabolic rate and hematologic findings point toward a local origin. As to whether a number of teeth need extraction or not, it could only be decided by direct examination of the patient.

The role played by heredity in such cases might obtain only after all the commoner factors have been ruled out. In the child's case, if the oral hygiene is really good, a tentative suggestion would be to examine her for obstruction of the upper respiratory passages, as mouth breathing is a fairly common cause of inflammation of the anterior gingivae in children. Again, since she is in the transition age between deciduous and permanent dentitions, the bleeding may be associated with eruption of teeth.

CHRONIC PROSTATITIS

To the Editor:—One frequently runs into cases of chronic prostatitis, nonspecific, in men past 50 years. Their prostate gland may show a moderate amount of enlargement on palpation. On massage the secretion is loaded with pus cells and a motile bacillus. In the past the only treatment used with these cases was weekly prostatic massage plus occasional passing of a sound. This seldom seems to clear them up. Is there any recent new treatment for these obstinate cases?

Eugene C. Lowe, M.D., Miami, Fla.

ANSWER.—A varying degree of nonspecific chronic prostatitis is common in men over 50 years of age. In the majority of cases the infection is of minor degree and causes few if any symptoms. It rarely becomes acute. However, when the prostatic secretion is found to be loaded with pus cells, it can cause local symptoms and can act as a focus of infection. Prostatic infection may be secondary to other foci, such as tonsils or teeth, and, in persistent cases, these should be excluded. Before treatment is instituted, urographic and cystoscopic studies should be made to exclude the presence of complications, such as prostatic calculi, calculus or tumor in the bladder. Vigorous prostatic massage, carried on daily or every other day for a period of several weeks, usually will reduce the degree of infection to a great extent. Infection in some of these cases may be controlled by various drugs and by antibiotics. Although sulfonamide drugs do not usually eliminate chronic prostatic infection, cases have been reported in which there has been material benefit. Many urologists have reported cases in which the infection was much reduced or eliminated by means of streptomycin or penicillin when employed in large doses. In the presence of coli organisms, streptomycin with alkalinization should be tried first, followed by penicillin, plus acidification. However, all methods of treatment may fail completely, as they have in the case under discussion. As a rule the infection subsides gradually with development of the patient's resistance, and, in the absence of symptoms, it can be largely disregarded.

SYPHILIS IN THE FATHER

To the Editor:—Will you advise me what antisyphilitic treatment is most likely to secure a healthy child in the following case: The husband, 31, denies infection, but admits having a positive Wassermann reaction for six years. He has had almost continuous treatment with oxophenarsine hydrochloride and bismuth compound for four years. Tests show no reduction in titer. The spinal fluid was normal on two examinations. The wife, 27, is pregnant two weeks. She has had negative reactions to three blood tests in the past year.

M.D., Pennsylvania.

ANSWER.—Even though her husband may have syphilis there is no likelihood that a seronegative woman who has never herself been shown to have the disease will give birth to a syphilitic infant. Antepartum infection of the fetus occurs uniformly via the placenta from spirochetemia in the mother. If the father is responsible for the infection of the fetus, it is through first transmitting syphilis to the mother and her transmitting it in turn to the unborn child. Infection of the fetus with syphilis for all practical purposes does not occur in the absence of maternal disease.

In the present instance the father has had his disease for at least six years, and his treatment has been apparently adequate according to accepted standards. Infectious mucocutaneous relapsing lesions are most prone to occur in the first two years of the disease and are uncommon after four to five years even in the absence of specific treatment. Failure of serologic response in spite of the active and prolonged treatment described is in favor of an infection of long standing. Semen is not infectious in the absence of open lesions of the genital tract. An amount of treatment such as is described would make infectious relapse most improbable, unless one is concerned with chronic relapsing disease, of which there is no indication from the history. The likelihood of transmission of infection to the mother from the father at this time is accordingly remote.

It is unusual to obtain a repeatedly negative blood serologic reaction for syphilis in a reliable laboratory in the presence of untreated syphilitic infection, particularly if the disease is active and recently acquired. On the basis of the information given, one would be forced to conclude that the mother is not infected with syphilis. The mother should be observed once monthly during the pregnancy. She should have a repetition of the blood serologic test for syphilis preferably at each of these visits, but as a minimum in the eighth month of the pregnancy and at the time of delivery. If maternal syphilis is diagnosed treatment with penicillin will give satisfactory results at almost any time in the pregnancy and should be commenced immediately, as described in the section on "The Prevention of Prenatal Syphilis" in the special article by the Syphilis Study Section of the National Institute of Health on the "Status of Penicillin in the Treatment of Syphilis" (J. A. M. A. **136**:877 [March 27] 1948).

Provided the mother remains seronegative for syphilis throughout the pregnancy, no special study of the newborn infant for the disease is necessary. As a final precaution a blood test should be taken on the infant at the age of four to six months, which if negative for syphilis will satisfactorily and completely rule out the possibility of congenital syphilis.

THYMUS GLAND

To the Editor:—In this small town we take care of our newborn babies, using pediatricians in cases requiring help. Of the 2 babies that were autopsied the cause of death was said to have been an enlarged thymus gland. Because of this, I have been routinely making roentgenograms of all infant thymus glands with the surprising result of finding more than one-half of these slightly to greatly enlarged. These infants were referred to roentgenologists for radiation treatment and discharged following a negative roentgenogram.

In Boston roentgenograms were made of the thymus in all children as part of their pretonsillar examination, and those who presented enlargement were not operated on. 1. Are we being slack in not having roentgenograms made of the thymus before tonsillectomy? 2. Am I placing too much importance on the problem?

M.D., Massachusetts.

ANSWER.—The dimensions of the thymus as shown by roentgen examination do not present conclusive evidence that an enlarged gland threatens the life or health of the infant. The thymus is rarely, if ever, sufficiently large to cause pressure on the trachea or the bronchial tree thus causing suffocation; infrequently an abscess or an infiltrating neoplasm might cause pressure on the adjacent organs. The thymus does not produce a hormone, nor is it a gland of internal secretion. The former conception of the status thymicolymphaticus has not been proved, and this condition is no longer accepted as a valid explanation of sudden death in infants or as a constitutional state.

In answering the questions propounded it may be stated briefly: 1. An enlarged thymus gland as shown on the roentgenogram is no longer regarded as an evidence of disease or a threat of sudden death. 2. Surgeons and pediatricians no longer require roentgenograms of the thorax to determine the size of the thymus before performing tonsillectomy.

Long years of investigation have failed to reveal the function of the thymus; its function being unknown, it is obvious that the dysfunction is equally obscure. Continued research may some day clear up the unsolved problem of the thymus gland.

GASTRIC MOTILITY AND ALTITUDE

To the Editor:—What is your opinion regarding a small residue of barium in the stomach six hours after a routine series of roentgenograms of the upper part of the gastrointestinal tract, without demonstrable lesions? Please furnish references on correlation of gastric motility and six hour retention of barium in high altitudes.

Captain, M.C.

ANSWER.—In the absence of any roentgenologically demonstrable duodenal or pyloric stenosis, or any other gastroduodenal lesion, the presence of a small amount of barium in the stomach after six hours is probably not of clinical significance. Fluoroscopic study of gastric peristalsis and ability to empty would be of interest in evaluation, as would a test meal with examination of gastric aspirate after five to seven hours.

A delay in gastric emptying in high altitudes has been reported and attributed to anoxemia of the tissues. It is questionable, however, whether this is merely transitory and attributable to a reflex inhibition of gastric motility secondary to the giddiness and other symptoms commonly experienced in sudden exposure to high altitudes.

Nimeh, W.: Emptying of the Normal Stomach in Altitudes, Rev. Gastroenterol. **14**:763-775, 1947.

BROMHIDROSIS

To the Editor:—Could you give me any information on the value of roentgen treatment in bromhidrosis? A patient has been afflicted with this condition for years. Have you any other suggestions as to therapy?

L. C. Gerlinger, M.D., Fostoria, Ohio.

ANSWER.—The query does not state whether the bromhidrosis is general or local. The treatment is similar to that for hyperhidrosis. Roentgen therapy is useful in many cases of local forms. Great care should be used lest excessive doses be employed that lead to untoward results. If moderate amounts of radiation are unsuccessful, it is wise to discontinue and try other methods. Excessive dryness and roentgen burns are worse than the original trouble. The use of chemicals, such as 1 to 10 per cent formaldehyde in alcohol, boric acid solution or powder, sodium bicarbonate 5 per cent in talcum, potassium permanganate, 1 per cent, as a paint, or as wet dressings, 1 to 1,000, is helpful. Aluminum chloride, 25 per cent, is the basis of many commercial preparations. For extreme degrees of hyperhidrosis and bromhidrosis of hands and feet, sympathectomy has been suggested. Iontophoresis is said to be effective temporarily. The patient may be excreting sweat of offensive odor after ingesting drugs such as valerian and asafetida, or foods like onion or garlic. Poor states of general health and emotional upsets may be a background to hyperhidrosis and bromhidrosis.

MALE STERILITY

To the Editor:—What is the newest form of treatment for a man with sperm count of 10,000,000 with 85 per cent motility, 50 per cent at the end of five hours, 85 per cent abnormal forms of all kinds. The wife is normal in every way. I have built up his general health; other physical abnormalities were not noted. He has received anterior pituitary lobe hormone by injection—100 units weekly for twelve weeks.

M.D., New York.

Answer.—More than one specimen of semen should be examined before it is concluded that the foregoing picture represents the patient's average production. If such proves to be the case, a testicular biopsy is indicated. If this shows hypoplasia, degeneration or atrophy of the seminiferous tubules, as is only too probable with semen as poor as the specimen described, then little benefit can be expected from any sort of treatment. If, on the other hand, the germinal epithelium proves to be in fairly good condition, further attempts may be made to stimulate it. The effect of gonadotropic therapy is uncertain and unpredictable, but it sometimes happens that one type succeeds where others fail. Hence equine and chorionic gonadotropins might be tried in the present case. In general, fertility is favored if a patient's basal metabolic rate is maintained at the plus 10 level. Carefully regulated administration of thyroid may be used as needed to accomplish this purpose.

OCULAR HEMORRHAGE

To the Editor:—Please furnish advice regarding treatment of a patient who is 65 years of age, arteriosclerotic, and is myopic—16 D.—in both eyes. He had a choroidal hemorrhage in the macular region of his left eye two months ago with resulting loss of central vision. Vision in his right eye is poor because of corneal opacities following corneal ulcers in childhood. What will (a) prevent any further hemorrhages and (b) improve his vision? O. M. Haarburger, M.D., Cape Town, Africa.

Answer.—(*a*) Rupture of the lamina vitrea in an elderly arteriosclerotic person with high myopia is not rare. The prognosis and treatment of this condition when complicated by macular choroidal hemorrhage is hopeless. He can be assured, however, that he will not become entirely blind, but will likely always be able to find his way about. Treatment with rutin, tocopherol and/or iodides (sodium or potassium) by mouth can be tried. Rest, both local and general, is advisable, and strenuous physical exertion must be avoided. If the arteriosclerosis is accompanied by vascular hypertension, this is particularly important. (*b*) Telescopic lenses may be tried, but the restricted field of view often is worse than the affliction. Full correction of the refractive error is advisable. The patient should be instructed to use his peripheral vision to the full capacity. Simple training along this line is often helpful. Corneal transplant of his left eye might be considered. The vision in this eye, however, might well be permanently affected as the result of nonuse over so long a period.

MALNUTRITION

To the Editor:—How does one go about putting weight on a person? My patient is a young woman of 27, married and has a child age 2. She is 5 feet, 1 inch (155 cm.) tall and weighs 95 pounds (43.1 Kg.). She seems normal in every way; viz., basal metabolic ratio, menstruation, chest, blood (hemoglobin, 78 per cent), development. Her appetite is only fair. I have tried high caloric diet and insulin, but instead of gaining she has lost 2 pounds (0.9 Kg.). I have been tempted to try testosterone propionate, since Dr. Fuller Albright suggested that it is the anabolic hormone. Would it do her any harm? If not, what dosage should I use?

M.D., Canada.

Answer.—The treatment of malnutrition is difficult. Whereas testosterone propionate will promote anabolism of many tissues, it should not be used on an essentially normal person such as the patient in question, because of the tendency to virilism. Furthermore, one can build up tissue only to a limited degree with this agent when one is dealing with an essentially normal patient.

HEMATURIA

To the Editor:—In a man aged 26 years hematuria was discovered for the first time during a routine urinanalysis March 1945. Renal function tests, clotting tests, intravenous pyelogram, intramuscular and intravenous dye injection, roentgenogram of the kidney and genitourinary tract failed to determine the source of bleeding. In July 1946 cystoscopy disclosed normal bladder, ureteral ostia, trigonum and vesical neck; catheters passed readily to both renal pelves; the urine returned clear with normal drip from the right side, slightly bloody from the left. Plain roentgenograms revealed no evidence of stone, and a left retrograde pyelogram revealed a perfectly normal kidney, pelvis and major and minor calices. Hematuria continued without pain or fever. Guinea pig tests in August 1945 and August 1946 were negative; in September 1945 tonsillectomy gave no improvement. From December 1945 to June 1946 cystoscopy and all other tests were repeated. In August 1946 cystoscopy and other tests were repeated with negative results. Hematuria continues in changing amount without interruption up to the present. Please give suggestions concerning diagnosis and treatment.

M.D., New Hampshire.

Answer.—In view of the duration of hematuria and the lack of other symptoms and signs, it is possible that the bleeding originates from one or more varices on the renal papillae or from a small angioma. The latter would be a more likely diagnosis, especially if hemangiomas are present elsewhere over the body. Repetition of the retrograde pyelogram may reveal slight fuzziness of the calices, which would speak for varices. The instillation of 1 or 2 per cent silver nitrate into the renal pelvis might be tried as a means of controlling the bleeding. If hemorrhages are severe enough to cause anemia or other disturbance, a nephrectomy is indicated.

THYROIDECTOMY IN AURICULAR FIBRILLATION

To the Editor:—Should surgery of the thyroid be contemplated in a woman aged 55 with an exophthalmic goiter and a basal metabolic rate of plus 38? She has an auricular fibrillation.

L. Edward Giovine, M.D., Woodside, N. Y.

Answer.—The presence of auricular fibrillation is not a contraindication to a subtotal thyroidectomy for exophthalmic goiter in a woman 55 years of age. The patient should be properly prepared for operation and the basal metabolism reduced to normal with the administration of propylthiouracil supplemented for one week preceding the operation with the administration of iodine. The risk of a thyroidectomy in a patient with heart disease is little greater than in a patient without heart disease, provided that adequate preoperative preparation is carried out.

CARBON DISULFIDE

To the Editor:—A young man, shortly after going to work in a rayon plant where he states that he is exposed to acetone fumes, developed a rather obscure illness consisting of arthralgias and slight fever. Laboratory work, electrocardiograms and appropriate roentgenograms all failed to reveal abnormality. The illness subsided spontaneously, and the patient returned to work. After forty-eight hours, the symptoms returned and again subsided on rest. Can you give me any information as to any toxic reactions to acetone or to the products used in rayon manufacture? Would there be any possible connection between this patient's exposure and his illness? M.D., Pennsylvania.

Answer.—Acetone, of all industrial solvents, is one of the least toxic. In attempts to fix tolerable limits 3,000 parts per million of acetone in air have been rejected as too stringent by one group devoted to standard provisions. This may be contrasted with the standard for carbon disulfide, which unofficially is 10 parts per million. Should this patient be employed in the manufacture of viscose rayon, the possibility of exposure to highly dangerous carbon disulfide should be explored. This substance provides the outstanding danger in that chemical process. Manifestations are legion, but the absence of the normal corneal reflex is the most suggestive single indication of chronic carbon disulfide involvement. Adequate discussions of the action of carbon disulfide may be found in: Johnstone, R. T.: "Occupational Medicine and Industrial Hygiene," St. Louis, C. V. Mosby Company, 1948, and Gordy, S. T., and Trumper, M.: Carbon Disulphide Poisoning, *Indust Med.* **9**:231, 1940.

TELEVISION SCREENS

To the Editor:—Is there harmful effect produced by the television screen? If so, how can this be minimized? Alfred Lilienfield, M.D., New York.

Answer.—It is believed that harmful radiation from the household television screen does not occur. Some experimental television screens may emit harmful radiation. This is not certain and it is being studied.

A PRESENT DAY RATIONALE FOR THE TREATMENT OF URINARY TUBERCULOSIS

Chairman's Address

REED M. NESBIT, M.D.
and
A. WAITE BOHNE, M.D.
Ann Arbor, Mich.

Streptomycin has been demonstrated to be effective in the treatment of many types of urinary tuberculosis, with the result that a new and hopeful attitude regarding the prognosis of the disease prevails. But new discoveries are often accepted and utilized by the public without an adequate orientation in thinking regarding the ultimate changes which may be brought about by the new agency. An example in point is modern air transportation. The public knows that our continent can be spanned by air in one day; yet New York and San Francisco are still five days apart in the thinking of most persons because of our orientation to earthbound travel. The present discussion is related to a reorientation of our thinking in the matter of treating urinary tuberculosis; for it is now evident that we should treat all patients with this disease by prolonged sanatorium care and streptomycin therapy whether the infection appears to be clinically bilateral or unilateral, and the following evidence is presented in support of this view.

Urologists have generally agreed that unilateral caseating renal tuberculosis does not heal spontaneously and, for this reason, have always advocated nephrectomy in its treatment. Likewise it is known that the prognosis in bilateral renal tuberculosis is poor, although there are several reports in the literature enumerating patients with bilateral disease who have survived for remarkably long periods of time.

Most urologists today are using streptomycin in treating urinary tuberculosis. There is a unanimity of opinion regarding the general effectiveness of this form of treatment, but time and experience are as yet lacking for an adequate evaluation of the method. Therefore, the precise indications for its use, the exact dosage and the optimal duration of treatment are yet to be disclosed by experience. How soon these factors can be determined is a matter of conjecture. The Veterans Administration is attempting to determine the optimal dosage, duration of treatment and method by observing large groups of patients treated by various plans of streptomycin administration; but even under the controlled conditions that prevail in this large scale study the final results will be long in appearing and will be related largely to a special group of patients—young male subjects.

The urologist today properly wonders how he should approach the matter of planning a course of treatment in any case of urogenital tuberculosis. His indecision is obviously not concerned with the treatment of frank bilateral disease, for there are no alternate methods in that situation. Streptomycin offers the only hope of suppressing the disease in such a circumstance. His concern is related rather to deciding between alternate regimens when he is confronted by a patient with unilateral infection. It is the purpose of the present inquiry to discuss the rationale of streptomycin therapy in the management of unilateral renal tuberculosis. Our investigation must include an evaluation of three important factors that have a significant bearing on the problem: (1) the effectiveness of streptomycin in the healing of tuberculous lesions in the urogenital tract and the risks inherent in streptomycin therapy, (2) the pathologic aspects of the disease and (3) the prognosis of patients who are treated for unilateral disease by nephrectomy alone.

EFFECTIVENESS OF STREPTOMYCIN IN TUBERCULOUS LESIONS IN THE UROGENITAL TRACT; RISKS OF TREATMENT

Most investigators agree that streptomycin will cause an arrest or an improvement in the majority of the tuberculous lesions that occur in the urinary tract. At the present time the best results appear to have been attained in two groups of cases: (1) those having residual cystitis following nephrectomy for clinically unilateral disease and (2) those who have lesions of one or both kidneys which can be diagnosed by the observation of tubercle bacilli and pus in the urine obtained by ureteral catheterization, but which show no roentgen evidence of destruction in the kidney. Recently Lattimer and others[1] asserted that only renal lesions of this type have responded favorably to streptomycin therapy. These investigators have had a large experience in the antibiotic therapy of urogenital tuberculosis, and their opinions, which are based on accurate and exhaustive case studies, may be looked on with respect. The experience of these authors, however large, is limited, and their declarations that advanced renal lesions—i. e., lesions which are visible in the pyelogram—will not become arrested by means of streptomycin therapy, cannot be regarded as final or determinative. There are already several reports from competent and reliable observers enumerating cases of this type, in which there was healing under antibiotic treatment and the patients remained free from

pus and tubercle bacilli for long periods of time. A case in point is one which we now have under our observation in the clinic of the University of Michigan Hospital (case report).

L. W., a 22 year old woman, had suffered from moderately advanced bilateral pulmonary tuberculosis for four years, which was complicated by tuberculous peritonitis in 1946. At that time asymptomatic pyuria developed, which prompted an investigation of the urinary tract, and bilateral destructive renal lesions were demonstrated. Streptomycin therapy was begun in June 1947, 1.5 Gm. per day being given for seventy days while she remained in the sanatorium. The urine became free from pus and organisms after streptomycin therapy and had remained free from all evidences of infection after twelve months. Ninety days after streptomycin treatment was begun the patient was found to have a ureteral stricture at the bladder level on the right, and also evidence of a massive cicatrix in the left kidney which appeared to threaten its survival. A right cutaneous ureterectomy was performed in October 1947, and the patient was clinically well as of the date of writing. Pyelographic examinations in May 1948 revealed no abnormalities on the right side as well as a remarkable improvement of the left kidney, and the urine was still free from pus or tubercle bacilli that could be demonstrated by all methods of identification.

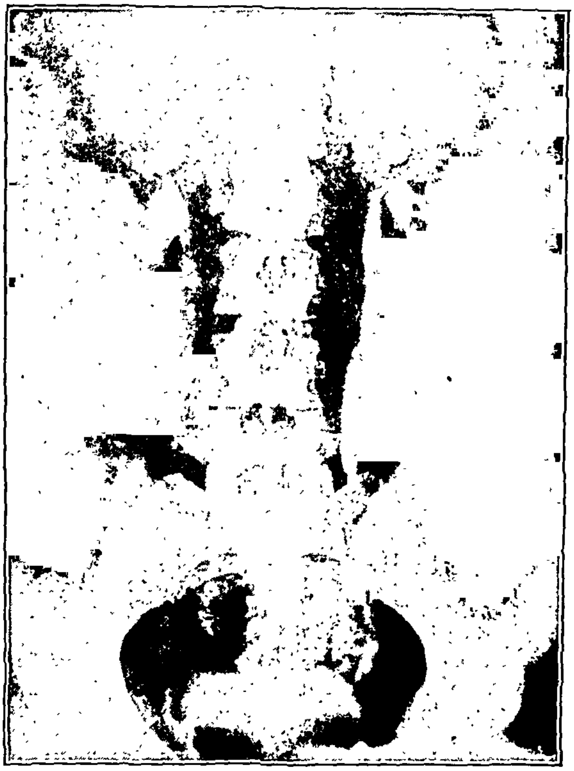

Fig. 1.—Pyelogram prior to streptomycin therapy.

Final opinions regarding the optimal streptomycin dosage and the duration of treatment must be delayed until adequate data have accumulated. At the present time there appears to be a tendency toward the favoring of smaller dosages than those originally employed. Among the reasons for this attitude are the factors of expense and the avoidance of toxicity. Neither of these items should be regarded as extravagant when the suppression of a lethal disease is the object of the expenditure. At the present moment the evidence in favor of a dose smaller than 2 Gm. per day in the control of urinary tuberculosis is at best tenuous, if not completely lacking. In our own small series of 29 cases that have been followed up sufficiently long for significant observation, it has been interesting to note that the only failures or relapses have occurred in patients who were treated with doses of streptomycin that were less than 2 Gm. per day. To be sure, most of the patients have suffered some loss of vestibular function, and a few have demonstrated impairment of hearing, but they are alive and, although a bit wobbly, are all enjoying remissions, and we and they are content with the outcome.

PATHOLOGIC ASPECTS OF THE DISEASE

Any rationale for the treatment of disease must be predicated on a basic understanding of its pathologic aspects. This is particularly true of urinary tuberculosis, which is a metastatic disease, and the blood-borne organisms are invariably deposited in both kidneys as well as in other tissues of the body. The classic study of Harris [2] demonstrated that tuberculosis of the urinary tract occurred frequently among tuberculous children who had bone involvement but rarely among children who had only pulmonary lesions. Conclusive evidence regarding the universal bilaterality of the disease was furnished by the monumental studies of Medlar [3] in 1926. This investigator examined serial sections of the kidneys from persons who had died of pulmonary tuberculosis and found that bilateral cortical infections were present in all the kidneys. The majority of the lesions were minimal in size and showed evidences of healing. Only a few of the hundred and fifty thousand sections that he studied showed lesions that the clinician might be able to demonstrate by pyelography. Yet all the kidneys were doubtless capable of producing tuberculous

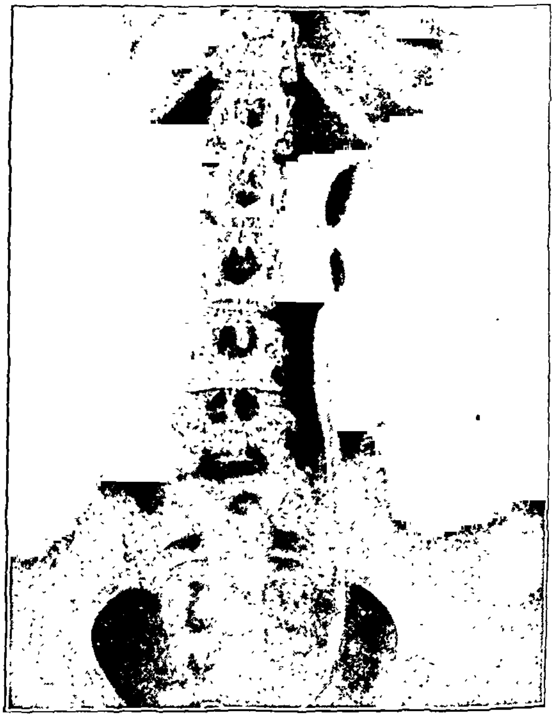

Fig. 2.—Retrograde pyelograde pyelogram (left) after streptomycin therapy, disclosing constriction of the pelvis. (The urine was normal.)

bacilluria. Additional data relating to this subject have been recently provided by this same pathologist. At the Boston meeting of the American Urological Association in May of this year (1948) Dr. Medlar read a report entitled "Post Mortem Compared with Clinical Diagnosis of Genito-Urinary Tuberculosis in Adult Males."[4] His observations were based on 5,424 necropsies performed on male subjects over 16 years of age at Bellevue Hospital. He found that nearly all renal infections were bilateral and that other organs of the urogenital tract invariably were involved. One of his conclusions based on this study was:

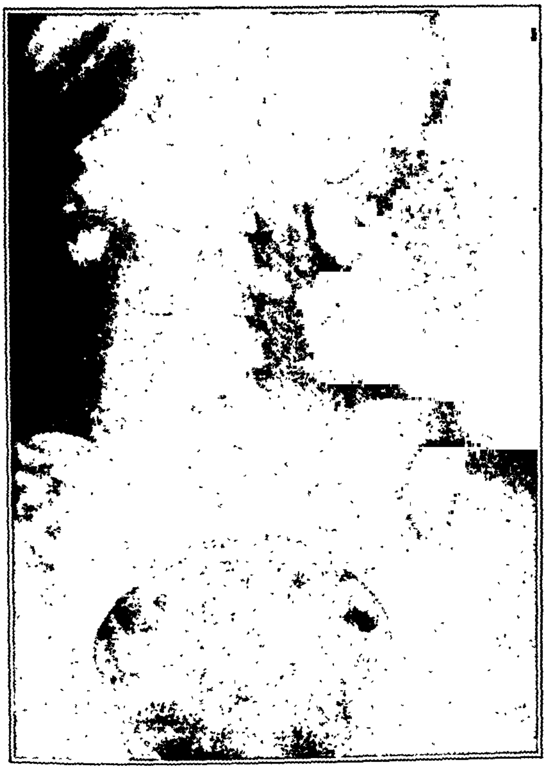

Fig. 3.—Excretory pyelogram after streptomycin therapy, showing dilatation of the left side of the pelvis above the constrictive lesion.

> The clinical management of a patient with genito-urinary tuberculosis should be based upon a clear concept of the pathogenesis of tuberculosis as a whole. If the intention is to prevent a further spread of the disease within the system by surgical removal of the organ in which tuberculosis is recognized, the data presented in this paper indicate that already other organs are affected and the surgical procedure is too late to obtain the desired results.

PROGNOSIS WITH NEPHRECTOMY ALONE FOR CLINICALLY UNILATERAL DISEASE

Another factor which must be considered in viewing the present problem is that which relates to the prognosis following nephrectomy for clinically unilateral disease. This important facet of the picture is one that unfortunately has received only scant attention by urologists in the past. To be sure, there is an extensive literature devoted to the discussion of various other aspects of the problem, and there has been a wide acceptance of the doctrine that nephrectomy is indicated in patients who are demonstrated clinically to have tuberculosis confined to one kidney. The clinician has perhaps been forced to depend on the implication that when the disease was properly diagnosed and appropriately treated the patient got well, for he has been told repeatedly that nephrectomy must be performed if the patient is to recover; but analyses of the results of nephrectomy have been conspicuously lacking in the literature. An outstanding contribution in this regard is that which was reported by Wildbolz[5] of Switzerland in 1925. Wildbolz reported that 59 per cent of his nephrectomized patients became cured after operation, the majority of the remaining patients dying of renal or some other form of tuberculosis. There have been only three series of cases reported in this country which can be utilized in deriving conclusions regarding the value of nephrectomy: that of Giles[6] in 1937, dealing with 96 patients operated on at the Squier Clinic; the Mayo Clinic series of 1,131 patients reported by Emmett and Kibler[7] in 1938, and 153 cases that were reported by Nesbit, Keitzer and Lynn[8] in 1945. These three series of cases provide an aggregate of 1,380 patients who were treated in recognized clinics and in whom the criteria for operation were such that a reasonable expectation for cure must have prevailed at the time that nephrectomy was performed. Yet only about half of the patients were alive five years after operation. Emmett and Kibler analyzed their cases on the basis of survival in relation to the urinary observations in

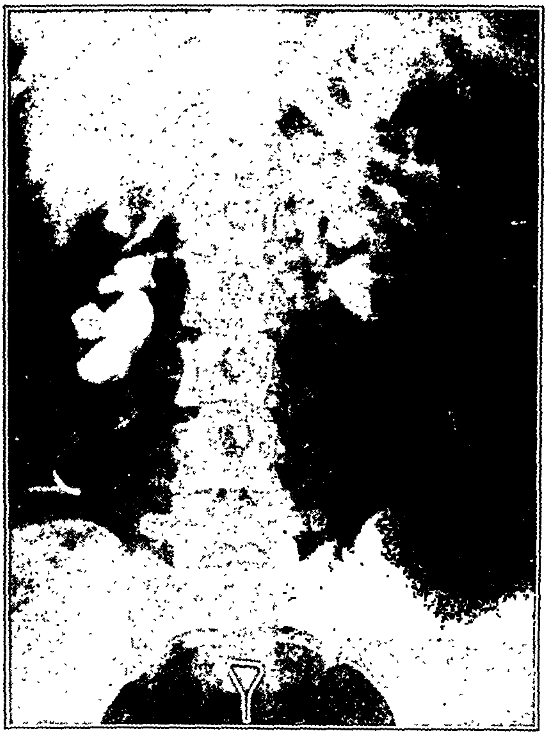

Fig. 4.—Pyelogram made one year after streptomycin therapy and seven months after right cutaneous ureterostomy, with apparent regression of the constrictive lesion on the left. (The urine was still normal.)

the "good" kidney and observed that when the urine was free from pus cells the chance for a five year cure was 43.5 per cent and the chance for a five year cure when the urine from the good kidney was free from both pus cells and tubercle bacilli was 50 per cent. The Michigan series roughly paralleled these figures, with two thirds of our cases showing five year clinical cures when the urine from the good kidney was free from pus and tubercle bacilli. These clinical results manifestly demonstrate the value of operation in treating this devastating malady, but a candid assay of the data also indicates how dismally nephrectomy has failed in nearly half the cases.

A recent reanalysis of our cases was made for the purpose of determining the factors influencing the prognosis. Complete data are available in 121 of the cases and are enumerated in the accompanying chart. These data reveal that the incidence of genital or pulmonary lesions is about the same among the patients enjoying good results as those who died or who became worse after operation, whereas the incidence of severe cystitis and the condition of the good kidney do importantly influence the prognosis. It is clearly evident that the most favorable prognosis is to be encountered in the patient who has minimal or no cystitis and whose "good" kidney is free from evidences of either obstruction or infection; but freedom from these involvements does not guarantee a favorable outcome of nephrectomy. The criterion which appears to stand out as an indication of a bad prognosis is the presence of severe cystitis. Only 4 of the patients who died had been free from this complication. Nevertheless, one third of the cured patients had had severe cystitis. It is obvious that the prognosis in any case of renal tuberculosis is hazardous and that nephrectomy is not a specific cure for the disease.

*Summary of Data on Patients Treated by Nephrectomy**

	Genital, B. & J. Lesions, Etc.		Pulmonary Lesions			Cystitis		Pyelograms (Good Kidney)		Urine in Good Kidney		
	Absent	Present	None	Minimal	Moderately or Far Advanced	None or Minimal	Severe	Normal	Hydronephrosis	Normal	Pus	Tubercle Bacilli
Cured patients	34	12	41	3	2	32	14	41	1	41	5	1
Improved but not cured	13	9	20	1	1	19	3	20	0	21	1	1
Total	47	21	61	4	3	51	17	61	1	62	6	2
Living but worse	3	1	3	1	0	3	1	1	?	0	4	1
Dead	21	28	35	9	5	4	45	9	11	29	20	17
Total	24	29	38	10	5	7	46	10	11+	29	24	18

* There were 27 deaths due to renal tuberculosis, 14 (miliary 4) to other types of tuberculosis, 6 to hydronephrosis and 2 to Addison's disease (total 49). Fifteen of the cured patients and 4 of the dead patients had only minimal or no cystitis, no genital or pulmonary disease and normal observations in pyelograms and normal urine on the side that was not diseased.

SUMMARY AND CONCLUSIONS

A reorientation of our habits of thinking in the matter of treating urinary tuberculosis is necessitated by the advent of streptomycin. Clinicians are now treating several types of urinary tuberculosis with prolonged sanatorium care and full courses of streptomycin therapy: six months should be regarded as the minimum of sanatorium care while longer periods of time are often necessary, and ninety to one hundred and twenty days of antibiotic therapy are recommended. The dosage of streptomycin is at present variable—the matter being in the investigative stage—but many have found from 1.5 to 2.0 Gm. per day to be the most effective dosage. The types of conditions that are now being treated in this manner include bilateral renal tuberculosis, residual cystitis following nephrectomy and clinically unilateral kidney lesions when there are no pyelographic evidences of the disease. At the present time most urologists are treating, by nephrectomy, the clinically unilateral lesions of the kidney that can be demonstrated by roentgenogram, and many are advocating short preoperative and postoperative courses of streptomycin to prevent the traumatic spread of the disease. When the rationale of streptomycin therapy is based on the knowledge that urinary tuberculosis is universally bilateral and that nephrectomy alone cures only about half the patients, it would seem to be illogical to withhold any therapeutic measure which might enhance the complete healing of the patient's tuberculosis. The nephrectomized patient should be afforded the same advantages of modern therapy that are considered appropriate for other patients suffering from bilateral renal tuberculosis.

Surgical removal of the grossly diseased kidney is a well accepted principle, but perhaps in the future nephrectomy can be relegated to a position below that of streptomycin and rest in the order of importance. Since it has been shown that even ulcerative renal lesions will sometimes heal during treatment with streptomycin, it would be reasonable to withhold surgical treatment, at least temporarily, in all cases of clinically unilateral renal tuberculosis. The patient should be placed on a regimen of strict rest in a sanatorium and should receive 2.0 Gm. daily of streptomycin for sixty days. At the end of this time a survey should be made to determine, by urinalyses and retrograde pyelography, the results of treatment. When the studies indicate conspicuous evidences of healing the plan of treatment should be continued for an additional sixty days, with repeated observations of the state of the lesion thereafter. The patient should then complete a minimum period of six months of sanatorium care or longer if necessary, in accordance with the needs for treatment.

If at the termination of the initial sixty day period, the patient's symptoms remain unaltered and pus and tubercle bacilli are still present in the urine obtained by ureteral catheter, nephrectomy would be indicated. Postoperatively streptomycin therapy should be continued for sixty days longer and the patient kept at rest for the prescribed six month period, or longer if need be.

Although this plan certainly will not prove efficacious in eliminating the necessity for nephrectomy in all instances, it promises, when nephrectomy is carried out, to diminish the likelihood of miliary dissemination during operation and to militate against wound disruption following nephrectomy, and it will also serve to influence favorably the subsidence of other metastatic lesions which might still be active in the patient, particularly those in the remaining kidney, thus enhancing his chances for recovery. Our reorientation in thinking regarding the treatment of urinary tuberculosis must be predicated on a realization that operation has failed dismally in the treatment of this disease, for in the past the nephrectomized patient has had only an even chance for survival.

CONTROL OF CANCER OF THE UTERUS

Report of a Ten Year Experiment

CATHARINE MACFARLANE, M.D.
MARGARET C STURGIS, M.D.
and
FAITH S. FETTERMAN, M.D.
Philadelphia

During the ten years prior to writing, members of the Department of Gynecology of the Woman's Medical College of Pennsylvania have been conducting a clinical research on the periodic pelvic examination of presumably well women. This research was undertaken for the purpose of determining the value of such examinations in detecting cancer of the uterus, particularly the cervix, in an early and curable stage and in detecting lesions of the cervix commonly believed to predispose to cancer.

In 1938 and 1939, we succeeded in interesting the women of Philadelphia in this project. As a result, 1,319 white women, 30 to 80 years of age, presumably well, volunteered to come for pelvic examination twice a year for five years.

Table 1.—*Pelvic Cancers*

Location	Number of Cancers
Cervix uteri	4
Corpus uteri	2
Ovary	1
Vaginal wall	1
Total	8

Most of the volunteers appreciated the importance of the undertaking as a contribution to medical science as well as of value to themselves. With others it was a matter of passing interest. When told once or twice that they were in good condition, they grew weary of well-doing and dropped from the ranks. Some died. Some moved away. Nevertheless, we were able to make a five year report at the 1944 meeting of the American Medical Association in Philadelphia on 545 continuing volunteers.

At that time, Dr. Ludvig Hektoen, Chairman of the Committee on Clinical Research of the American Medical Association, expressed the opinion that this group of women should be followed up immediately. The examining physicians and the majority of the volunteers were eager to do this. Efforts were made to rekindle the interest of those who had dropped from the ranks. As a result, we are able to report today on 732 volunteers who have been examined more or less regularly over a ten year period.

In the first examination of the 1,319 presumably well women, three squamous cell cancers of the cervix were discovered (volunteers 68, 174 and 430). Two of these were discovered on microscopic examination of areas of papillary erosion that had aroused no suspicion of malignant growth and that had been excised by the Sturmdorf technic. The third was observed on biopsy of an extensive and suspicious looking area of papillary erosion. These 3 women were treated with radium and showed no evidence of recurrence nine years after treatment.

A cancer of the uterine body was discovered on the first examination of volunteer 1140. On account of medical handicaps, treatment was limited to radium and roentgen rays. There was recurrence after nine years.

A fourth cancer of the cervix was discovered on the eleventh visit of volunteer 527. There were no symptoms, but examination revealed a smooth red polypoid growth, 1 cm. in diameter, protruding through the external os. This proved to be an adenocarcinoma. Radium needles were inserted into the growth for 1,300 mg. hours, and 2,400 mg. hours were given in the uterine cavity. Unfortunately, pyometra, general systemic infection and severe gastrointestinal symptoms developed, which made it impossible to give adequate treatment with either radium or roentgen rays. The patient died of recurrence after two years.

Table 2.—*Social Status and Childbearing*

Category	In Original 1,319 Volunteers	In Continuing 732 Volunteers
Single nulliparous women	188	80
Married nulliparous women	224	113
Parous women	907	539

Adenocarcinoma of the endometrium was discovered on microscopic examination of a myomatous uterus removed supravaginally from volunteer 898 in March 1942. She showed no evidence of recurrence after six years.

A cystic tumor of the ovary was discovered on the ninth visit of volunteer 176. Operation showed this to be a rapidly growing malignant tumor, with extension to the peritoneum. This patient died of recurrence after sixteen months.

Table 3.—*Incidence of Cancer of the Cervix in 3,000 Gynecologic Patients*

Number of Cases	Type	Age	Cancer of Cervix
1,000	Single white nulliparous	20-77	6
1,000	Married white nulliparous	20-79	14
1,000	Married white parous	20-79	37

A cancer of the anterior vaginal wall was discovered by volunteer 1037 (a physician) just before she was due for her fifteenth visit. The growth was excised and irradiated, but the volunteer died of recurrence in the lungs after three months.

This brings up to eight the cancers of the pelvic organs discovered in our continuing group of 732 volunteers over a period of ten years. The chief interest

---

Read before the Section on Obstetrics and Gynecology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

lies in the four cancers of the cervix. Each of these occurred in a woman who had borne a child. Four cancers of the cervix seem a small number to have developed in a group of 732 women over a period of ten years.

Our volunteers are classified according to social status and childbearing in table 2.

Deducting from the parous group 10 women whose children were born by cesarean section (whereby trauma to the cervix was eliminated), we still have 529 parous women in the continuing group.

Table 3 shows the incidence of cancer of the cervix in white women, 30 to 80 years of age, according to a previous study of admissions to the gynecologic services of the Woman's Hospital and to the Hospital of the Woman's Medical College.

While the incidence of cancer would naturally be greater in patients admitted to hospitals than in presumably well women, it is interesting to compare these figures with the observations in our research group.

TABLE 4.—*Benign Lesions of the Pelvic Organs*

Type of Lesion	Number
Inflammatory lesions of the cervix	489
Myomatous tumors of the uterus	193
Mucous polyps of the cervix	140
Cystic tumors of the ovary	40
Leukoplakic areas of the cervix	3
Papillomas of the cervix	2
Tuberculous ulcer of the vagina	1
Total	868

TABLE 5.—*Inflammatory Lesions of the Cervix*

Lesions	Number of Lesions
Endocervicitis	68
Cervicitis	53
Cervicitis with erosion	
Simple	100
Follicular	38
Papillary	105
Nonspecified	125
Total	489

On this basis, we might expect to find one cancer of the cervix in our 193 nulliparous women and twenty cancers of the cervix in our 529 parous women. So far, over a period of ten years, we have found no cancers of the cervix in our nulliparous group and only four cancers of the cervix in our parous group.

Some light is thrown on this situation when benign lesions of the pelvic organs discovered in the volunteer group are considered. In addition to the eight cancers, eight hundred and sixty-eight benign lesions of the pelvic organs were discovered in the volunteers from the begining of the research until April 1, 1948.

Most important of these benign lesions from the point of view of cancer are the 489 inflammatory lesions of the cervix. These are classified in table 5.

Some 214 of these inflammatory lesions of the cervix have been eliminated by operation, conization or cauterization. My colleagues and I believe that the development of some cancers of the cervix has been prevented by the elimination of these inflammatory lesions.

This research has cost a great deal of time, money and energy. Its results are not spectacular. Perhaps its greatest value has been educational. We must admit that in the control of cancer, education is a mighty weapon.

Our clinic is called a Cancer Research Clinic. It differs from prevention or detection clinics in that, after the original group of volunteers was recruited, no new volunteers were added. The volunteers made no financial contribution. The examining physicians gave their services without charge. The Woman's Medical College gave clinic space and nursing service.

The expense of secretarial service, of a part time medical statistician, stationery, supplies, postage, record cards, examination of pathologic specimens and other such items varied from $150 to $200 per month. This was met by grants from the American Medical Association, the International Cancer Research Foundation, the New York Medical Women's Association, the Pennsylvania Division of the Women's Field Army of the American Cancer Society and the Philadelphia Division of the American Cancer Society and gifts from private persons.

We can claim that as a result of the research three cancers of the cervix were discovered in an early stage, were treated promptly and showed no signs of recurrence after nine years; two hundred and fourteen inflammatory lesions of the cervix were discovered and eliminated, and 1,000 women and their relatives and friends have been taught the value of periodic pelvic examination.

CONCLUSIONS

Early cancer of the cervix and lesions predisposing to cancer can be detected in presumably well women by means of periodic pelvic examination. Every woman 30 years of age and over who has borne a child should be examined once a year or twice a year if inflammatory lesions of the cervix are present. Inflammatory lesions of the cervix should be eliminated.

136 South Sixteenth Street.

ABSTRACT OF DISCUSSION

DR. B. Z. CASHMAN, Pittsburgh: For more than thirty years some of us have been stressing the importance of periodic examinations for detecting cancer of the cervix, but it was Catherine Macfarlane who had the vision, industry and persuasiveness to induce 1,000 women to submit to examinations *faithfully and persistently. You have heard her results.* This is an excellent record and establishes the value of periodic examination in detecting cancer of the uterus in the curable stage. The low incidence of carcinoma of the cervix in her series is striking. This is suggestive that her policy of cleaning up the inflammatory lesions and the polypi of the cervix prevented cancer of the cervix. We, of the University of Pittsburgh, have been interested in the same problem but made a different approach. We have carefully examined the cervix of every woman who passed through our hands in office and hospital. If there was pronounced cervicitis present, or if symptoms of cervicitis were not relieved by conservative treatment, deep cauterization of the cervix was advised. If the patient was scheduled for surgical treatment, regardless of its nature, the opportunity was used to treat cervicitis by deep cauterization under the same anesthesia. After a series of 10,000 cases had been accumulated we attempted to determine in how many of these patients cancer of the cervix subsequently developed. Three surveys have been made. Only 3 cases of cancer of the cervix have been found in this entire group. Whether we prevented the development of carcinoma of the cervix by eliminating chronic cervicitis, as we formerly believed, or whether we destroyed cancer in its incipient stages, is of academic interest only. The important fact is that invasive cancer occurred in only a small percentage ((0.03 per cent) of this group. Until we learn more about cancer of the cervix, the laborious methods of Dr. Macfarlane and Dr. Papanicolaou, and of our own or some similar procedure, seems to be the only true preventive measures now known. One does not need to wait for the discovery of the cause of cancer. One does not need to wait even for better methods of treatment. Doctors have now the means for eliminating cancer of the cervix if it is discovered early. It is not a problem for gynecologists alone, for gynecologists see only a small percentage of the women of this country. The opportunity lies in the hands of the general practitioners.

Dr. Augusta Webster, Chicago: This is a unique study, one which I believe to be of great significance. These examinees were carefully screened, and no persons with symptoms were accepted for this project in clinical research. The same physicians have conducted the ten year study with 732 of the original 1,000 examinees cooperating. The continuity of the project, from the point of view of participation of both patient and physician, is a most valuable factor; too often changing personnel leads to variation in the interpretation of the same condition. The term precancerous has long been under fire, and the purists have preferred to avoid its use. The clinician, however, has always been suspicious of the relation of certain conditions to malignancy, but has lacked specific evidence to support the idea. Seven hundred and thirty-two women between the ages of 30 and 80 years were in this group who had a goodly number of minor, seemingly harmless, pelvic lesions, but in whom only eight pelvic malignant growths developed over a ten year period; four of these were cervical cancers. The four cervical malignant growths were discovered in the incipient stage, resulting in nine year cures for 3 patients. Over two hundred benign conditions were treated during the ten year period. The relatively large number of benign conditions eradicated and the small number of cancers found would certainly suggest that at least some precursors of cancer were destroyed. In apparently healthy persons many conditions may be discovered by careful physical examinations while in an asymptomatic subclinical phase. At the Cancer Prevention Center of Chicago, of 6,000 apparently healthy women, 1,015 were found to have a lacerated hypertrophied cervix, 1,288 had erosions and 223 had polyps. These figures overlap, as some women had more than one condition. In 318 instances, or 4.9 per cent, biopsy was recommended to rule out malignancy. All these persons were referred to their own family doctors for diagnostic study and treatment. It is not the intention of the Cancer Detection Clinics to alarm the examinee or to encourage other than conservative treatment of conditions found. Rather the objective is to promote effective preventive medicine and thus to insure longer life and better health to the examinees.

Dr. J. Hofbauer, Cincinnati: A rational approach in prevention of malignant conditions of the uterine cervix requires adequate knowledge of the specific etiologic and conditioning factors involved. The weight of opinion favors the view that there is an earlier predisposing phase when cellular elements that have been stimulated to proliferation present pictures of potential malignant disorder. Proliferation of polygonal cells—derivatives of the undifferentiated basal infra-epithelial cells—with the formation of one or more layers, has been observed as the cervical response to a variety of morphogenetic stimuli, notably chronic irritation, gestation and disturbed balance of the specific endocrine mechanism of the uterine cervix. It is these tissue changes with their associated deviations in functional equilibrium which have been invoked as the prologue of the cervical epithelial drama. The specific mechanism, however, accountable for the transformation of such hyperplastic preinvasive epithelium into carcinoma, is not known. The concept that cervical malignant conditions represent the sequelae of trauma incident to childbirth, cervical lacerations and erosions had remained unchallenged long enough to have become the traditionally accepted explanation. Observations made by my colleagues and me of unmistakable early cervical carcinoma in areas distinct from lacerations or erosions necessitated the search for other etiologic factors. Our experimental studies showed for the first time that the implantation into the musculature of laboratory animals of bits of fresh anterior pituitary substance evokes a rapid sequence of extensive growth phenomena of the cervical epithelium and of the uterine glands. Correlation of these observations with the recognition of occurrence of hyperplastic changes in the prepituitary as the result of repeated pregnancies created the conception of the specific hormone-induced growth phenomena in the uterine cervix—the anterior pituitary and ovarian—as predisposing factors of malignancy. Pursuit of studies concerned with the identification of inhibitors of growth responses to hormonal stimuli seems to hold the key to progress in the fascinating subject.

Dr. Catherine Macfarlane: Last year in this country more than 16,000 women died of cancer of the uterus. At the present time early detection is the best method available to curb the ravages of this disease. Early detection is a function of the general practitioner. In this mighty conflict he forms the first line of defense.

BRIAN BLADES, M.D.
Washington, D. C.

Empyema of the thorax has become a rare disease. This is particularly true of the postpneumococcic variety and applies to other pleural abscesses resulting from trauma and other causes. A few years ago it was a well known lesion with a significant mortality rate and troublesome morbidity and the source of controversial opinions on details of treatment. Students of medicine were warned of the frequency of complicating empyema following pneumonia, and residents dreaded the management of drainage tubes and suction apparatus. Today it is possible and probably likely that young surgeons might not have the opportunity to study an old-fashioned case of empyema of the thorax during an extended training period.

The first dramatic reduction in the incidence of postpneumococcic empyema followed the almost universal use of the sulfonamide drugs for pneumonia. For example, in 1,250 patients with pneumonia treated with the sulfonamide drugs, Dowling [1] reported an incidence of 1.9 per cent of complicating empyema. Even greater reductions in the frequency of complicating empyema following pneumonia have been reported by other authors.[2]

The almost universal use of penicillin in infections of the respiratory tract has further reduced the frequency of pleural abscesses to a figure ranging from 0 to 0.08 per cent in most series. This remarkable agent has the advantage over the sulfonamide derivatives of a strong antibacterial action when given systematically and the retention of its potency in the presence of blood and pus. Moreover, the proved low toxicity of the mold makes it possible to give enormous doses both parenterally and locally with a minimal chance of dangerous or distressing side effects. The addition of streptomycin to the antibiotic armamentarium of treatment has furnished another effectual method to combat organisms not vulnerable to penicillin.

It becomes apparent that empyema should be considered as a medical disease, with the goal of aborting frank abscesses rather than waiting for a well formed localized abscess to develop. It is important, however,

to remember that the use of these agents, which have made empyema a rare lesion, may attenuate abscess formations and change the clinical manifestations of the disease so decidedly that a diagnosis frequently cannot be made, if one thinks in terms of the type of empyema common before antibiotic therapy was available.

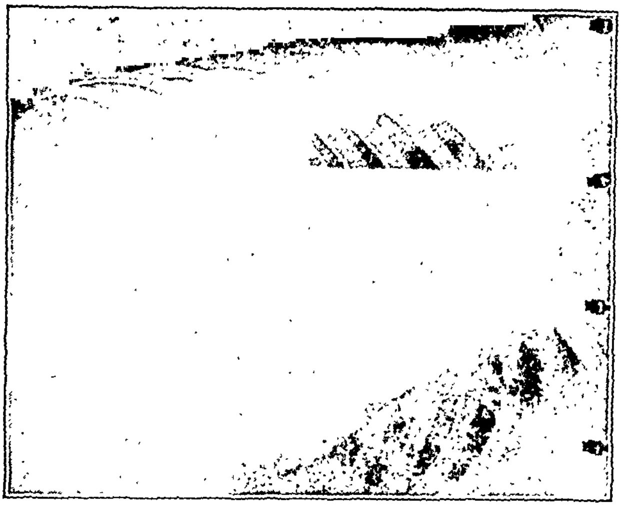

Fig. 1.—*Roentgenogram taken in lateral decubitus position, demonstrating a huge empyema cavity and empyema necessitans and showing the thoracic wall at the site of empyema necessitans.*

During the past war, in a study made by Blades, Hamilton and Dugan [3] of 24 cases of empyema treated with penicillin, it appeared that the early and vigorous parenteral and intrapleural use of penicillin, as soon as infected fluid appeared in the pleura, would abort the formation of frank abscess in many cases. Further experience with this type of treatment verifies the original impression. It was pointed out, however, by the same authors, that if frank thick pus forms, surgical drainage should be established and that sterile empyema is not cured empyema. Subsequent studies with both penicillin and streptomycin in the management of empyema have not altered these observations.

Proper employment of antibiotics in the treatment of empyema requires two considerations. First, the continued use of antibiotics, either locally or parenterally, without surgical intervention, after the formation of thick pus which cannot be aspirated, and therefore precludes early and complete reexpansion of the lung, should be condemned. Second, the realization that after severe pneumonia, coupled with pleural effusion, there may be some residual empyema, usually in the posterior gutter, which may escape detection for weeks or months.

An example of the misuse of penicillin in a case of traumatic empyema may be illustrated by case 1.

REPORT OF CASES

Case 1.—A young man, 23 years of age, suffered severe and multiple injuries in a serious automobile accident, including a laceration of the liver and multiple rib fractures. A hemothorax developed on the right, which received little attention, probably because of the severe abdominal injuries which required a laparotomy. Figure 1 shows the appearance of the chest eight weeks after the accident. In preceding weeks blood had been aspirated from the pleura and penicillin injected into the space. The fluid in the pleura gradually thickened and assumed the appearance of frank pus. No organisms were seen in the cultures. A week before operation thoracentesis failed to reveal pus. It is obvious that at this time the fluid was so thick that it could not be withdrawn through an ordinary needle.

A huge sterile pleural abscess developed, and after eight weeks empyema necessitans developed, pointing on the anterior thoracic wall. A thoracostomy for drainage of the empyema and incision of the thoracic wall abscess resulted in prompt healing, with no apparent permanent disability.

It is probable that early and vigorous attempts to free the pleura of fluid would have prevented the formation of the infected hemothorax and consequent empyema. The seriousness of the injury and the circumstances surrounding the accident made this somewhat difficult. Even after the hemothorax became infected, the possibility of decortication of the lung might have been considered, provided that the patient's general condition did not preclude a thoracotomy. The important lesson to be gained from this case, however, is that the use of penicillin produced a sterile abscess, but the foreign body in the pleura prevented reexpansion of the lung and healing, and, finally, by purely mechanical means sterile pus produced empyema necessitans.

This is an extreme example of the misuse of penicillin. These circumstances are more likely to occur in a case of traumatic empyema. It appears that the greatest difficulty results from the false sense of security obtained by sterilization of pus in the pleura without regard for the mechanical factors involved in the healing of an empyema cavity.

An interesting and treacherous attenuation of empyema which may follow antibiotic therapy is illustrated in case 2.

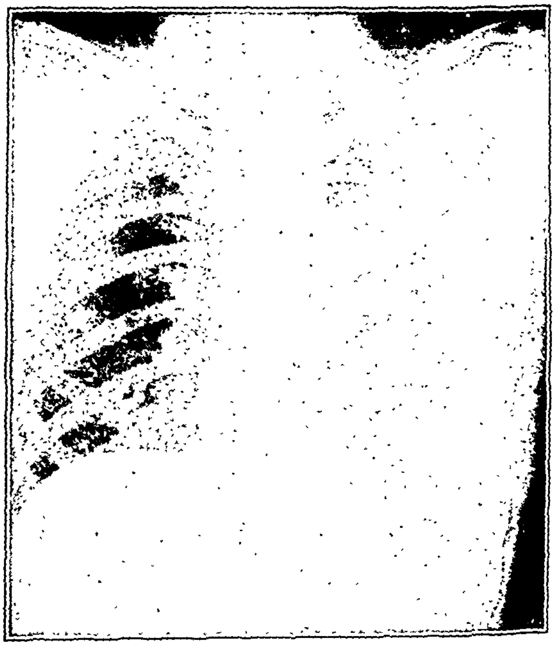

Fig. 2.—*Roentgenogram revealing pleural effusion which accumulated rapidly after the onset of acute illness. The fluid was sterile.*

Case 2.—A young man, 21 years of age, had a severe cold and was confined to his home for about two weeks with low grade fever, cough and expectoration. After this period he experienced a sudden chill and high temperature, ranging from 39 to 40 C. (102 to 104 F.), and massive pleural effusion developed rapidly. Penicillin was given in doses of 50,000 units every three hours and later increased to 100,000 units every three hours. This treatment was started immediately after the chill and fever. The fluid in the chest accumulated rapidly, and thoracenteses were required every two or three days for a period of about four weeks. Cultures of the pleural fluid revealed no organisms (fig. 2). After repeated aspirations, the pleural fluid seemed to disappear and the patient's temperature fell to normal with the exception of low grade fever every two or three days. The appearance of the roentgenogram of the chest six months after the onset of illness is shown in figure 3.

---

[3] Blades, B.; Hamilton, J. E. and Dugan, D. J.: Surgery **17**: 572, 1945.

Repeated examinations of sputum had revealed nothing of significance, and the tubercle bacilli had not been identified. The appearance of the roentgenogram of the chest was thought to indicate tuberculosis, and this patient was advised to observe strict bed rest for an indefinite period, until a positive diagnosis had been established. The patient observed strict bed rest for four months, and seven months after the onset of his illness the drainage of a small pleural abscess situated in the posterior gutter resulted in a cure. The pus contained Streptococcus hemolyticus.

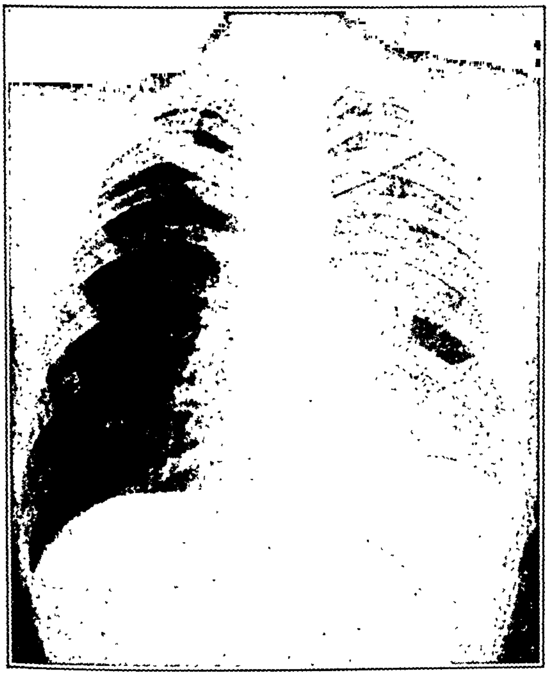

Fig. 3.—Appearance of the chest six months after the onset of acute illness. A diagnosis of tuberculosis was made based on the roentgenogram.

This is an example of attenuation of severe streptococcic pneumonia and pleural effusion with the mistaken diagnosis of tuberculosis. Before the antibiotics were available, the erroneous diagnosis of unresolved pneumonia in cases of empyema of the thorax was common. The frequency of this mistake has been tremendously reduced, but the error still occurs. Three cases similar to case 2 have been observed, and the patients with residual empyema were thought to have unresolved pneumonia. This impression delayed necessary surgical drainage for several months.

COMMENT

In this connection it is important to remember that parenteral administration of penicillin or streptomycin may render a pleural effusion temporarily sterile. If an antibiotic is also employed locally, the possibility is even greater. After weeks or months the bacteria debilitated by the antibiotic sometimes revive enough to multiply and produce an active purulent pyogenic infection.

The obvious advantages of penicillin over the sulfonamide derivatives in the treatment of pneumonia and in cases of potentially infected traumatic hemothorax are so apparent that they require no comment. Certain principles of the use of streptomycin in the treatment of pyogenic empyema will be mentioned later.

Based on my own clinical experiences and the experimental work of Romansky, the following therapeutic approach is suggested. In cases of frank pneumonia with classic severe onset—fever, chills and other classic symptoms—penicillin should be administered immediately. A dosage of 300,000 units in one of the repository products, e. g., penicillin in wax and oil or similar preparations, is suggested. If aqueous penicillin is to be used, a dosage of 25,000 to 50,000 units every three hours is desirable. In cases with known bacteremia or in established staphylococcic infections, 300,000 units should be given two to four times daily.

If pleural fluid appears, it is important that the local treatment be withheld until an attempt has been made to identify the organisms. An initial precise bacteriologic diagnosis may rule out the possibility of a tuberculous infection or establish it and serve as a guide for subsequent antibiotic therapy. In this connection the importance of the use of penicillinase in the laboratory deserves mention. Unless the precaution is observed, the cultures may remain sterile because of the inhibitory effect of penicillin. When penicillinase is employed, this inactivation is eliminated and a positive culture may be obtained.

The dangerous toxic effects of streptomycin have already been mentioned and are well known. Reductions in dosage of this agent have greatly diminished these side actions, but they still exist and must be considered. It is important to record, therefore, that the intrapleural use of streptomycin is followed by a rapid rise in blood levels, and, if the antibiotic is to be employed locally in the pleura, reductions in parenteral dosage may be advisable until the peak of the blood level from local use has been reduced. The experimental and clinical studies of Beattie and his co-workers have established that the maximum level from intrapleural use of streptomycin is reached in from one-half to one hour after it is placed in the pleura and then falls rapidly. It is practically eliminated within four hours. This important consideration is worth recording. Since experimental and clinical evidence indicates the desirability of using the antibiotic combination, that is, combining penicillin and streptomycin, there is even more importance in precise bacteriologic diagnosis before treatment begins.

CONCLUSION

Failure to establish a definite bacteriologic diagnosis in the seriously ill patient should not be an absolute contraindication to antibiotic therapy, particularly in the case of penicillin. The significant toxic effects of streptomycin, however, make it important not to employ this agent unless there are absolute indications based on bacteriologic evidence. There are few exceptions to this principle. Relatively few organisms, which are not vulnerable to penicillin but respond to streptomycin therapy, produce pleural abscesses. The principal ones are the hemolytic influenza bacillus, Friedländer's bacillus and a few rare gram-negative bacteria.

If the intrapleural use of an antibiotic is indicated in the presence of fluid or blood in the pleura, it should be combined with systemic administration of the proper agent. If the fluid or blood continues to thicken and form frank pus, drainage or decortication plus drainage should be employed.

ABSTRACT OF DISCUSSION

Dr. Edward M. Kent, Pittsburgh: There is general agreement among surgeons in this country with everything that Dr. Blades has said concerning empyema thoracis. The two most significant observations have been that new problems have arisen in the treatment of empyema as a result of the use of antibiotics and that this complication of pneumonia resulting from the pneumococcus is seen much more rarely now than it has been in the past. It may be felt by some that it is unusual to present a paper on a problem of decreasing clinical incidence. However, I consider it highly important to do so in this instance. There are two chief reasons for this attitude: First, it is the ultimate goal of the members of the medical profession to do themselves out of a job, as it were, and strides of significant proportions have been made in that direction. However, we tend to lose sight of these accomplishments because the scope of medical practice has been extended more rapidly than it has been reduced. We are making progress in the fight to lessen or eliminate the need of surgery in the treatment of infections. Similar progress is being made in other fields of surgical endeavor excepting, of course, the repair of the results of trauma and the correction of anatomic defects. Secondly, I consider the presentation of this matter timely because, as Dr. Blades has so clearly pointed out, there are certain new problems which have been created as the result of the use of the antibiotics in the treatment of pneumonia and empyema. Dr. Blades has shown us what these new problems are, how they are anticipated and the way that he has managed them from a clinical point of view. In addition, he has sounded certain warnings which we all will do well to heed. I, for one, am in complete agreement with what he has said.

Dr. Thomas H. Burford, St. Louis: I would like to underscore what Dr. Blades has said concerning the increasing complexity with which the problem of empyema is now vested. It is true that what empyema has lost in frequency it has gained in complexity. At the Barnes Hospital, where my associates and I are now seeing approximately a twentieth of the amount of empyema that we saw in the days before sulfonamide drugs and antibiotics, we encounter problems of a vastly altered nature, and it is significant that in only a small percentage of the cases of empyema that we now see—particularly of the postpneumonitic type—is drainage done. They require a more radical type of approach. One patient whose disease was diagnosed as virus pneumonia partially recovered from the primary disease with a stiff regimen of antibiotics. A residual shadow in the posterior right side of the chest was later observed and diagnosed as carcinoma. It was not until a needle aspiration was done that it was found to be empyema. Because of the fact that the process had existed for about three months when seen, we did not drain but elected to resect the entire empyema sac. Another patient had almost certainly had typical pneumonia of pneumococcic type and had been treated intensively with penicillin. He came to us with a chest full of pus, from which nothing could be grown twelve weeks after the discovery of the empyema. Again, primary drainage was not done. A primary decortication was performed with prompt recovery. I would like to say a word about the problem of empyema in childhood. It is particularly important, now that practically all children with pneumonia are treated intensively from the very beginning with one or a combination of antibiotics, that the treatment of empyema, which may in rare cases develop, not be neglected. It is still mandatory in the very young group to institute "water-seal" intercostal drainage as soon as infected fluid is discovered.

AUREOMYCIN, A NEW ANTIBIOTIC

Results of Laboratory Studies and of Clinical Use in 100 Cases of Bacterial Infections

MAXWELL FINLAND, M.D.
HARVEY SHIELDS COLLINS, M.D.
and
TOM FITE PAINE Jr., M.D.
Boston

Unpublished data made available to us[1] suggested that the new antibiotic, aureomycin, was of low toxicity, was effective in vitro against a large variety of gram-positive and gram-negative bacteria and was particularly effective in experimental infections with rickettsias and with viruses of the psittacosis-lymphogranuloma venereum group. Clinical trials to determine its field of usefulness, therefore, seemed warranted. The results of the oral use of this antibiotic in 100 cases of a variety of bacterial infections are of sufficient interest to warrant this report. A brief résumé of the results of laboratory studies carried out in the course of this clinical study is also included. Further details will be presented in separate communications.

BACTERIOLOGIC STUDIES

Sensitivity of Bacteria.—Tests for sensitivity to aureomycin were carried out by tube dilution or streak plate methods on one hundred and eighty-six strains of pathogenic bacteria recently isolated from patients at the Boston City Hospital.[2] Strains of hemolytic streptococci, pneumococci, gonococci and meningococci were almost completely inhibited by aureomycin in concentrations of 1 microgram per cubic centimeter or less. Staphylococci and most strains of gram-negative bacilli, including typhoid and other Salmonella, were inhibited by 25 micrograms per cubic centimeter or less. Only strains of Proteus vulgaris and of pyocyaneus were moderately resistant and required from 100 to 250 micrograms per cubic centimeter for complete inhibition. There was no evidence of cross resistance with penicillin, streptomycin, polymyxin or bacitracin in any of the organisms tested. On a weight basis aureomycin was less effective than penicillin against most of the coccic organisms, but was about as effective as streptomycin against most of the gram-negative bacilli.

Stability.—Aureomycin was supplied as the hydrochloride in a dry powder in sealed ampules and in capsules. In these forms it has maintained its potency apparently unaltered for at least seven months at room temperature. It has also retained its activity for long periods in solutions that are kept frozen at —20 C. Concentrated solutions (2 mg. per cubic centimeter) in distilled water at p_H 4 retained their activity for over two weeks at 4 C. and also at 37 C. The potency of solutions in a slightly alkaline medium, in concentrations of 200 micrograms per cubic centimeter incorpo-

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston.

This is a summary of material presented by the authors at a Conference on Aureomycin at the New York Academy of Sciences, July 21, 1948. This work was carried out with the technical assistance of Clare Wilcox, Janice M. Bryan and Paul F. Frank and was aided by a grant from the *United States Public Health Service. Dr. E. Buist Wells* participated in the latter part of this study.

[1] The data were provided by workers of the Lederle Laboratories Division, American Cyanamid Company, who also provided generous supplies of the antibiotic.

[2] The strains were isolated and identified in the Bacteriology Laboratory of the Mallory Institute of Pathology by Marion E. Lamb and A. Kathleen Daly.

rated in blood agar or 8 micrograms per cubic centimeter in saline solution, plasma or broth deteriorated rather rapidly at 37 C. and somewhat less rapidly at 4 C.

Other Factors Influencing Aureomycin Activity.—The size of the inoculum influences the concentration of aureomycin required to inhibit the growth of bacteria as tested by the tube dilution method, but has little effect, within a wide range of inoculum size, on the end points which are obtained by a surface streak method. Aureomycin is effective only against vigorously multiplying organisms, but not against fully grown or resting cultures. Aureomycin is much more effective in an acid than in an alkaline medium—the reverse of streptomycin. Attempts to demonstrate an aureomycin-inhibiting substance similar to penicillinase in filtrates of aureomycin-resistant organisms or in extracts of disrupted cells of a number of bacterial species were without success. The activity of aureomycin on cultures is not diminished by incubation in a candle jar, but higher degrees of anaerobiasis may decrease its effectiveness. Filtration of solutions of aureomycin in water, broth or urine through Seitz, Mandler or sintered glass filters does not appreciably reduce the activity of the aureomycin.

Resistance.—There was no significant tendency for the development of resistance to aureomycin in organisms either in vitro or in vivo. Of six strains of organisms repeatedly subcultured on graded concentrations of aureomycin, only one, a strain of Aerobacter aerogenes, increased in resistance thirty-two fold during thirty transfers, and no further increase in resistance occurred during forty additional transfers; the other five strains retained their original sensitivity throughout seventy subcultures. In contrast to streptomycin, resistant variants could not readily be obtained by exposure of large numbers of bacteria to high concentrations of aureomycin. All organisms of the same species isolated from the same patient before, during and after treatment with aureomycin for varying periods up to one month or longer were equally sensitive to this antibiotic.[3]

ABSORPTION AND EXCRETION

Aureomycin appears rapidly in the urine and is excreted continuously for two or three days after a single dose of 0.5 or 0.75 Gm. The highest concentrations, ranging up to 256 micrograms per cubic centimeter, are present in the urine from two to sixteen hours, and the maximum rate of excretion in the urine occurs between four and eight hours after the dose, suggesting that the optimum interval between oral doses should be about six to eight hours. Activity equivalent to between 12 and 15 per cent of a single orally administered dose can be recovered in the urine with the crude methods available.[4] Plasma levels after oral doses of up to 1 Gm. every six hours have usually been found to be about 2 micrograms per cubic centimeter or less, but the methods used were not satisfactory. Aureomycin could not be detected in bile obtained from the common bile duct during oral administration of the antibiotic, although it was not inactivated by bile in vitro.

CLINICAL RESULTS

The number of cases of various bacterial infections, the range of dosage used and a rough estimate of the clinical effect in 100 patients is shown in the table. Most of the patients in whom the results are listed as "doubtful" showed definite clinical and bacteriologic evidence of improvement during treatment with aureomycin, but either the results were transient or the role of the antibiotic in effecting these results could not be evaluated. The doses that were used were necessarily empiric and were increased whenever possible, in the same or in subsequent cases when the results were not optimal. No other chemotherapy or antibiotics were used during the aureomycin administration, although such agents had previously been given without success in some of the cases, particularly those with infections of the urinary tract. The results in some of the groups of cases may be summarized briefly.

Gonococcic Urethritis.—The over-all results in these cases with the doses used were satisfactory, but they were distinctly inferior to those obtained with a single injection of 300,000 units of penicillin in a prolonging agent. A number of different dosage schedules were used. Failures were most frequent among patients treated during a single day with two or three doses, or with a total of 1.5 Gm. or less. In patients receiving such doses, urethral discharge was usually still present on the day after treatment was given even when gonococci could not be demonstrated in smears or cultures at that time. Larger doses given for two days gave results approximating more closely those obtained with penicillin in the same clinic.

Summary of Results of Oral Aureomycin Therapy in 100 Patients with Bacterial Infection

Diagnosis	Number of Patients	Total Dose		Results		
		Grams	Days	Good	Doubtful	Failed

* Drs. Thomas F. Kaiser and Francis C. Regan and Mrs. Helen Trousdale assisted in the study of these cases.

† Four of these cases were in children; the fifth was in an adult.

‡ This patient also received 20 mg. intramuscularly every twelve hours.

§ Seven of these patients were given two separate courses of aureomycin for relapses of infection and are each listed twice under "Results."

Pneumococcic Pneumonia.—Of the 4 patients only 1 was over 60 years old and had a severe illness with jaundice, and in him treatment was started on the fourth day. The others were under 25 years old, and treatment in them was begun on the first or second day of their illness, which was mild or moderate. Each of the 4 patients had a single lobe involved, and only 1 had bacteremia before treatment was started. In each instance the temperature reached normal and the patient was clinically much improved within eighteen to thirty-six hours after the first dose of aureomycin. Pneumococci disappeared rapidly from the sputum and could not be identified by any method after the second day of treatment. The results in these cases were comparable to those obtained with adequate doses of penicillin or sulfadiazine.

---

[3] Paine, T. F., Jr.; Collins, H. S., and Finland, M.: Bacteriologic Studies on Aureomycin, J. Bact. 56: 489 (Oct.) 1948.

[4] Collins, H. S.; Paine, T. F., Jr.; Wells, E. B., and Finland, M.: Urinary Excretion of Aureomycin (Preliminary Report), Proc. Soc. Exper. Biol. & Med., to be published.

Meningococcemia.—One patient with headache, high fever and diffuse and rapidly spreading rash was treated eighteen hours after the onset of symptoms. The patient was much improved and afebrile within eighteen hours after the first dose. A blood culture, taken before the first dose, was positive for group I Meningococcus, and subsequent cultures were negative.

Typhoid Fever.—Four of the 5 cases of typhoid were in children, and in them treatment was started between the fifth and tenth day of the illness. They all had positive blood cultures before treatment, and all cultures of blood, urine and stools were negative after two or three days of aureomycin therapy. Symptomatic improvement began soon after treatment in only 1 case, but was steady and more gradual over a few days in the other 3. The fifth patient was 60 years old, and aureomycin was started in him four days after a relapse of infection with severe symptoms and bacteremia, which persisted for six days after this therapy was started. The patient then gradually improved, but his course was complicated by intestinal hemorrhage and by symptoms suggesting a perforation.

Typhoid Carrier.—One patient was known to have positive stool cultures repeatedly for at least a year before treatment was started and was the probable source of at least 2 fatal cases in a nursing home. She was given 250 mg. by mouth every eight hours for thirty-one days. During this time daily stool cultures were made, and only 1, obtained eight days after treatment was started, was positive for typhoid bacilli; the other stool cultures were all negative, but a culture of duodenal drainage material obtained on the last day of therapy was positive for typhoid bacilli. The stools again became positive two weeks after the treatment was stopped. The patient's gallbladder was subsequently removed, and its contents yielded a pure culture of typhoid bacilli. Common duct bile obtained by T tube after the operation in this case did not inhibit the action of aureomycin. Oral therapy with aureomycin was resumed after the operation, but there was no evidence of antibiotic activity in the bile during therapy with doses of 0.5 Gm. every six hours.

Salmonella Infections.—The illness in each of the 3 patients with Salmonella infections was unusually severe. The enteritis in 1 of the patients with an infection due to S. newport was improved, and in this patient the stools became formed and less frequent after aureomycin therapy, but the other patient with a similar infection with bacteremia died. The causative organism could not be recovered from the stools after treatment was started in the former, but they persisted in the latter throughout three days of treatment. In the patient with S. suipestifer bacteremia, the organisms persisted in the blood throughout eleven days of oral and intramuscular aureomycin therapy. A large intervertebral abscess and bilateral psoas abscesses were found at autopsy, and the organisms were cultured from the pus of these abscesses, from the cardiac blood and from other organs post mortem.

Colon Bacillemia.—A woman with colon bacillus bacteremia associated with jaundice, enlarged liver and an epigastric mass was improved clinically during treatment, but positive blood cultures were obtained and chills recurred after several days of aureomycin therapy. This patient died after an intestinal hemorrhage, and there was no autopsy.

Urinary Tract Infections.—The 16 patients with infection of the urinary tract who were chosen for treatment with aureomycin, with the exception of 1 with acute pyelonephritis occurring during pregnancy, all had infections of long duration, had failed to obtain any prolonged remission from many different types of therapy and had many complicating factors which militated against a favorable response. Most of them had had prolonged urinary retention, frequent instrumentation, prostatectomy, urolithiasis and recurrent acute and chronic cystitis and pyelonephritis. In the majority, the urine obtained just prior to aureomycin therapy yielded a pure culture of a single organism. Only 4 of these patients were hospitalized during the period of aureomycin therapy.[5]

In general, the pyuria in these patients diminished significantly during treatment and disappeared entirely in half of the patients while the treatment was still being given. Symptomatic relief occurred at the same time in most instances. The specimens of urine became highly acid and remained so throughout the treatment. Cultures of the urine became and remained sterile during treatment in most of the patients. In some of them, however, strains of proteus and pyocyaneus, and in 2 instances colon bacilli, either first appeared or persisted during aureomycin therapy. Infection recurred within a few days after this treatment was stopped in most of these patients, and either the same or different types of organisms were then found. The most persistent organism was Proteus vulgaris, but Pseudomonas aeruginosa also could not be eradicated. These organisms, as already noted, were the most resistant to aureomycin. Good results of a permanent nature were, therefore, infrequent in these cases of chronic infections of the urinary tract. Temporary relief, either slight or moderate, resulted in two thirds of these patients.

Nonspecific Urethritis.—Two patients were treated for urethritis which had persisted in spite of repeated treatment with penicillin, sulfonamide drugs and streptomycin. Cultures of the urethral discharge were negative for gonococci in both cases, and in 1 patient a pleuropneumonia-like organism was isolated. In the latter, a course of 9 Gm. of aureomycin by mouth over a period of six days resulted in fairly prompt symptomatic improvement with complete disappearance of urethral discharge, and subsequent cultures were negative. The other patient received 11 Gm. in five days and had rapid symptomatic improvement. His discharge had completely ceased before treatment was ended, and the infection was completely gone within eleven days.

TOXICITY

Toxic effects were minimal and infrequent. The commonest complaint during large oral doses of aureomycin was looseness of the bowels, with frequent and bulky stools, but true diarrhea was uncommon. Normal bowel action again occurred when treatment with the drug was discontinued or when the dose was temporarily decreased. Nausea and occasionally vomiting occurred after one or more doses in a few patients, but could not always be related to the treatment. An occasional patient with cystitis complained of a disagreeable sensation in the pelvis, which may have been related to the high acidity of urine during treatment with large doses. No other symptoms were noted.

---

[5] Seven of these 16 patients received two separate courses of aureomycin about two or three weeks apart.

Anemia attributable to the drug did not occur, and no depression in the cells in the granulocytic series was observed. There was no evidence of renal irritation as manifested by rising nonprotein nitrogen level in the blood, albuminuria or the appearance of cellular elements in the urine. There were no instances of jaundice or any other evidence of liver impairment developing after treatment was started. No fever or rashes definitely ascribable to the drug were observed. Drug fever was suspected in a child who had a recurrent elevation of temperature without symptoms after being almost afebrile after treatment for typhoid. A single dose of 200 mg. given subsequently, after the temperature had remained normal, failed to reproduce fever or symptoms, so that the relation of the drug to the recurrent fever could not be evaluated.

CONCLUSIONS

These observations suggest that aureomycin has definite antibacterial activity against many micro-organisms, including coccic and bacillary forms, and it may prove useful in the treatment of infections with organisms that are resistant to penicillin or to streptomycin.

Aureomycin given by mouth, in the doses used, appeared to have a definite beneficial effect in coccic infections. The results in cases of gonorrhea were inferior to those obtained with adequate doses of penicillin. The results in some of the patients with typhoid and Salmonella infections appeared to be favorable, but in most of the cases the effects were equivocal. In the infections of the urinary tract, considering the types of cases treated, the results were favorable and were probably comparable, if not superior, to those obtained with the use of streptomycin or sulfonamide drugs in similar cases. Infections with Proteus vulgaris and Pseudomonas aeruginosa, however, were not much benefited by aureomycin. The only evidence of toxicity was the occurrence of loose bowel movements when large doses were given by mouth. Resistant organisms did not develop during treatment with aureomycin, and resistant variants could not readily be produced in vitro.

While the observations of other workers, both in experimental animals and in human beings, suggest that the major field of usefulness of aureomycin may be in the treatment of infections with rickettsias or with viruses of the psittacosis-lymphogranuloma venereum group, the results in the present cases suggest that aureomycin may be useful in a large variety of bacterial infections. It therefore deserves a more extended clinical trial.

Hemometakinesia.—The concept of hemodynamics, to which the term hemometakinesia has been applied, provides, it is believed, a more rational approach to the management of certain forms of peripheral vascular disease than now exists. This concept is based on certain observations concerning the physiology of the circulation which established the presence of spontaneous and even rhythmic fluctuations in the volume of organs, primarily attributable changes in the volume of the blood within the part. These observations, which suggest that there is a continuous shifting back and forth of blood from one part of the body to another, seem to indicate the existence of a well regulated "borrowing-lending" mechanism which permits the body to utilize its limited blood volume in the most effective manner to meet variations in local requirements.—DeBakey, Michael E.; Burch, George E., and Ray, Thorpe, *The Journal of the Michigan State Medical Society*, June 1948.

TREATMENT IN A PSYCHOSOMATIC CLINIC

Preliminary Report

HERBERT S. RIPLEY, M.D.
STEWART WOLF, M.D.
and
HAROLD G. WOLFF, M.D.
New York

The treatment of the great number of patients with bodily disturbances and with emotional reactions occurring as part of the human organism's response to adverse life situations is an urgent medical problem. The present report is based on experiences in treatment with 889 such patients seen in a newly organized medical outpatient clinic over a period of two years. Six hundred and ninety of them were followed up for more than a year.

METHOD

The patients ranged in age between 5 and 69 years. Sixty per cent were female, and 40 per cent were male. They suffered chiefly from bronchial asthma, hypertension, vasomotor rhinitis, migraine, urticaria, hypoglycemia, dermatitis, peptic ulcer, mucous colitis, ulcerative colitis and phenomena of muscle tension.

In addition to the usual medical history and examination with appropriate laboratory tests, a personality study was done. Special note was made of the family and cultural background. The state of the patient's health was correlated with events, overt activities, attitudes and emotional responses. The objective was to understand the motivations and mechanisms of disturbed function. Treatment was aimed at altering the disordered pattern, so that the patient might achieve more adequate utilization of his capacities toward a greater satisfaction and a more salutary integration. Insofar as was possible, physiologic changes, qualitative and quantitative, were correlated with the emotional reactions and behavior pattern of the patient under varying life situations. Then an attempt was usually made to explain to the patient what had been happening to him, in order that perplexity might be replaced by a grasp of the dynamic mechanisms at work. The past experiences and reactions were integrated with the present in order to increase insight into his life adaptation.

RESULTS

Of the 690 patients, 113 were considered by their physicians to be symptomatically and basically improved. Two hundred and thirty-four were considered only symptomatically improved and 343 unimproved. One hundred and ninety-one of the 343 patients in the unimproved category attended the clinic for less than a month, and of these 82 received no treatment. If those who received no treatment were excluded, 19 per cent were basically improved, 38 per cent were symptomatically improved and 43 per cent were unimproved.

Thirty-one per cent discontinued coming to the clinic without any explanation. Follow-up studies revealed that about 60 per cent of these felt that they had improved. They were not, however, included in either of the aforementioned improved categories.

The designation symptomatic improvement was applied to those patients who had shown a definite and

sustained diminution in signs and symptoms over a period of at least a year. Basic improvement depended on the symptomatically improved persons having encountered a major threat in their life situation and having shown a reorientation in outlook by meeting it in a more constructive way and without symptoms.

EVALUATION OF VARIOUS THERAPEUTIC PROCEDURES

No absolute distinctions between therapeutic procedures could be made, and no one method could be administered in pure culture. Nevertheless, each physician delineated as far as was possible the treatments used and the value of each. The chief procedures and the number of cases in which they were used successfully were as follows:

Reassurance and emotional support	309
Free expression of conflicts and feelings	304
Advice regarding attitudes, habits and activities	173
Explanation of psychophysiologic processes	140
Symptomatic drug therapy	123
Intravenous use of "sodium amytal" (sodium isoamylethylbarbiturate)	112
Ruling out neoplastic and infectious disease	112
Dealing with other members of the family	101
Development of insight	99
Analysis of emotional development	91
Attempts to modify situation	71
Dream analysis	52
Help from Social Service Department	39

Reassurance and emotional support employed the human warmth of the physician and was helpful in enhancing the strength, faith and determination of the patients as well as in releasing inhibitions and repressions. It implied an understanding and tolerant attitude on the part of the physician and included recognition and praise for the assets and achievements of the patient. It also involved an unswerving interest in and concern for whatever problem or question the patient brought to the doctor. In short, without becoming too identified with the patient's problems the physician attempted to play the role of a strong authoritative, but not authoritarian, thoroughly dependable friend of the patient.

Free expression of conflicts and feelings through verbalization promoted a release of tension and often resulted in relief from anxiety and resentment and less need to act out emotional conflicts in a socially undesirable manner. Patients repeatedly stated that the free expression of their conflicts had given them a sense of relief and had aided in an understanding that was of the greatest help to them. Many complained of previously not having been permitted to talk, of having been told that there was nothing wrong, that they imagined they were ill or that they should forget their symptoms.

There appeared to be no short cut for allowing the patient to find out about himself by discussing himself frankly with a tolerant physician. When direct questions were asked bluntly the patient often felt that he was being cross examined, and an attitude of antagonism resulted. When he was allowed to talk at his own pace, however, relevant conflicts and significantly traumatic situations were relatively easily brought out.

The patients were encouraged to discuss the advantages and disadvantages of a given situation before making important decisions. Helping them to take independent action led to the development of a greater feeling of security and capacity to deal with ensuing problems. However, at certain times, when the psychodynamics had been clarified, direct practical advice was helpful in enabling them to break away from unhealthy fixed habit patterns. Such advice, coming from a physician, relieved the patient of responsibility and guilt, so that he could make constructive decisions which might otherwise have been delayed indefinitely.

An analysis of the emotional development during infancy, childhood and adult life was elicited by a biographic review and also by allowing the patient to associate freely about significant life events and his reactions to them. Recall and interpretation of dreams through spontaneous association by the patient facilitated the uncovering of emotional conflicts. The feeling of security engendered and the release of emotional repression aided in establishing healthier patterns of bodily function and in the development of more mature attitudes and behavior.

Intravenously administered "sodium amytal" was of value in the alleviation of troublesome symptoms, in the elucidation of dynamic mechanisms and in gaining therapeutic leverage.[1]

Frequently considerable improvement was achieved without the verbal expression of insight. Many patients who appeared to have developed some comprehension of the dynamics of their illnesses expressed it rarely or not at all. In some of these pride and a need for a feeling of self sufficiency interdicted an admission of improved integration. However, it was often conveyed indirectly to the physician.

The recording and measurement of physiologic disturbances and correlating them with the emotional reactions and behavior of the patient in varying life situations served to promote an understanding of the total biologic response and was often followed by improvement. This method was especially helpful to patients who came to the clinic perplexed about the nature of their disorder or apprehensive of its being a serious or perhaps fatal disease.

Interviews with other members of the family led to improvement in interpersonal relationships and decrease in anxieties and resentments in the home. These were usually carried out by the physician, but sometimes by the social service worker. The Social Service Department was also helpful in obtaining employment, arranging for convalescent care, making plans for children of patients and carrying out follow-up studies.

Drugs were used to afford symptomatic relief. They were usually employed to tide the patient over a difficult period in his illness, and their use was discontinued as soon as possible.

FORMULATION

It has been possible satisfactorily to treat in a medical outpatient department patients with various psychosomatic disorders and effect fundamental and lasting improvement in 1 out of 5 and at least symptomatic improvement in more than half of the group treated.

The bodily disorders and diseases were viewed as biologic reactions of defense against threats arising out of problems of interpersonal and situational adjustment.

The clinical course also gave support to the concept that the patient, in an effort to deal with adversity, invoked faulty emergency measures[2] which often led to illness and to tissue damage. The aim of the reaction patterns was often at variance with the conscious purposes of the patient,[3] and this accentuated the conflict.

A variety of types of relationship between patient and physician was found useful, as was flexibility with regard to the number and frequency of visits.

The depth of treatment attained depended on the ability of the patient to use his resources in developing improved patterns of reaction, rather than on the frequency of the interviews or the duration of the treatment. Diethelm[4] recognized the importance of flexibility in carrying out a plan of treatment. This was later emphasized by Alexander and French.[5]

An average of only nine hours per patient was spent, and no patient received more than eighty-five hours of clinic time during the two years of follow-up. At the end of the period of evaluation many of the patients were still being seen at intervals, but usually not more often than once a month.

The following assets presaged improvement:

1. Recognition of failure of present patterns of adjustment and desire for help
2. Confidence in and ability to cooperate with physician
3. Flexibility of personality structure
4. Disorder of recent origin
5. Capacity and willingness to assume responsibility in treatment
6. Past record of constructive interpersonal relationships
7. Past record of ability to derive satisfaction from occupation, religion, sports, lodges and other activities
8. Willingness of family to cooperate

The opposite characteristics were found among those for whom treatment was not successful. When a patient had not at least some of these assets, and if he had not shown some improvement after two months of this treatment, it was unlikely that he would benefit appreciably from a more prolonged period of treatment. There is not evidence enough as yet, however, to be sure of such a categoric generalization.

The most powerful therapeutic force stemmed from the ability of the physician and the clinic to inculcate in the patient faith in himself and the capacity to recognize and deal constructively with his problems. This usually involved a reorientation of attitude and entailed far more than a personal attachment to the physician. Only when he had acquired such faith and confidence was it possible for him to abandon costly inappropriate emergency patterns and deal more directly and constructively with threats and challenges of day to day living.

ABSTRACT OF DISCUSSION

DR. HENRY W. BROSIN, Chicago: I think that the report by Dr. Ripley and Dr. Wolf of 19 per cent basic improvement and 38 per cent symptomatic improvement would agree with the incidence observed in many other clinics; that is a respectable showing. I have every sympathy with their definitive phrasing in itemizing the thirteen methods used and the eight prognostic factors, but hope that in future studies the factors on which these various methods and prognostic criteria are based will be more clearly described. That is the heart of the problem in studying prognosis. This is an excellent study, but we need more definitive work in order to make it useful to the day to day practitioner. Flexibility in treatment is highly desirable, but the more precise definition of the methods used in terms of a specific patient-physician relationship is incumbent on the authors. There is no question in my mind that Dr. Ripley and his skilful associate have a systematic goal, but the actual details need fuller description. The authors point out that the necessity of learning the action patterns and the dynamics rather than the mere description of the patient's difficulties; I would add that we need more familiarity with these patterns. We need to be comfortable with the patient; otherwise, second rate settlements are made, even though these may result in favorable symptomatic improvement. I would like to call attention to the studies of Dr. Thomas French, who pointed out that perhaps one of the best methods of studying the efficacy of individual therapeutic technics—the actual relation between patient and physician—may be studied through the means of the individual unit of work done; a specific problem of the total constellation is carried from the beginning to a point of progress. A series of such units may give much better insight as to the methods, mechanics and basic improvements than a casual, a more superficial, total evaluation. The importance of sound recording for the future of prognostic studies, I think, cannot be overestimated.

DR. ROY R. GRINKER, Chicago: When one talks about psychotherapy it is necessary to understand exactly what one means. One can no longer equate it with some sort of refined common sense approach to a patient's problems, because it now includes procedures which have been highly developed and refined for specific disturbances and it consists of many highly specialized technics. In research in the field of psychotherapy there is no longer concern with statistical reports which state that so many patients were improved, cured or unimproved. These categories even with numbers give little information regarding the real problems of psychotherapy. It can be stated in general that interest lies in knowing what kinds of physicians treat what sorts of disturbances with what specific technics and get what results. By "disturbance" one does not mean a heading or a label in a diagnostic classification, but a specific dynamic formulation obtained from a detailed understanding of the patient's inner and external problems, his vulnerability to failure or success in special life situations with those problems and the methods with which he handles them. The methods with which one treats these disturbances must no longer be classified simply as psychotherapeutic. They must be classified scientifically in detail in terms of the exact procedures of intervention and their specific indications. Helping patients through social service, as one author stated, is not understandable as a system of treating patients. To say that there are thirteen methods which are all used at one time or another in the treatment of a single patient is interesting, but when is one method used? In what dynamic state does one use that one method to solve what problem, and with what results? Millions of dollars are being spent in psychiatric clinics, in psychosomatic clinics, and hundreds of persons are spending a great deal of time in applying therapeutic technics, and yet there is no awareness of the efficacy of any of these therapeutic ventures except in such general terms as have been stated in this paper. It is time to come to terms with specificity in relation to exactly defined entities of psychologic disturbances, in order that this may result in a specialized knowledge that may be retransmitted to the practitioner as "common sense."

DR. H. S. RIPLEY, New York: Perhaps we have covered too large a group of patients and too great a variety of clinical problems to give significant details about individual treatment; however, we have felt that it is important to try to delineate methods of treatment and make some approximation of their value. Our report is based on experience in the Psychosomatic Clinic at the New York Hospital, where the eleven physicians who were carrying out the treatment met in conferences to define the methods we have listed and evaluate their use. The result is a composite picture of their experiences. We need to continue to try to investigate carefully the questions raised by Dr. Brosin and Dr. Grinker. More specific indications for the various categories of treatment should be worked out by those studying psychosomatic problems; however, the complexity of the clinical syndromes and the variability in the personalities of the patients and the therapeutists make it necessary frequently to alter plans of treatment. The need for flexibility has to be kept in mind constantly.

VERIFIED REFRACTION

S. JUDD BEACH, M.D.
Portland, Maine

This paper describes a refraction routine in which throughout the examination one method of testing is used to check or verify another. In this way most of the common blunders are detected. This practice is particularly valuable for students and for general practitioners who perform a limited amount of refraction. It also has merit for experienced examiners.

At the Board examinations even the well prepared candidates usually show familiarity with only one way of refracting. The method chosen varies, but they use some one technic exclusively. Many of them can describe the theory of other common methods, but have never tried them. Others who have tried them never developed any facility with them. They reverted to their original technic, not because it was best, but because it was familiar.

At first thought this may seem rather commendable than otherwise. We are somewhat conditioned to the idea that if a refractionist can get results by any means, that is as much as can be expected of him. Why then should he not perfect himself in his one system and stick to it? There are several reasons. The first is somewhat theoretical. Surely with their pretensions to superior knowledge, ophthalmologists ought to be more widely informed. A more practical reason is the universal experience that every method, no matter how perfect in theory, fails occasionally. None is infallible. All of them are subject to error, but as they are based on different principles the same mistake does not occur with all. One method will check the accuracy of the others and will supplement them. This ought to be reason enough for all popular methods to be taught to all students. Another reason is that no refractionist is fitted to compare results of different technics until he can perform them dextrously. He does not know which is best.

In over half of all cases all methods of refraction, dials, cross cylinders, cycloplegia and fogging have almost identical results in the hands of experts. It is the other type of case, in which tests disagree, that causes trouble. This is the reason for outlining a refraction routine here which compares the results of different methods and yet is fast because it involves few changes of lenses. It is a good routine for teaching. It is also practical for office use. It is thorough and does not leave undone some test which may later reveal a mistake in the prescription and discredit the examiner.

Records properly begin with the history and visual acuity. The history will reveal certain symptoms which characterize certain anomalies of refraction. The complaints of presbyopic persons constitute an outstanding example. The data on visual acuity will show that different degrees of impairment of distant vision are consistent with different refractive errors, as for instance myopia.

Use of the pinhole is apt to give a rough idea of the possibility of correction.

With this information begins the streamlining of this routine. Preliminary noncycloplegic retinoscopy is the most revealing single test. This gives a preview of the patient's prescription. It is like getting the answer out of the back of the book. It does away with the fumbling called trial and error—mostly error—involved in so-called manifest refraction. Without it several changes of trial frame lenses have to be made before the examiner has any idea whether he is dealing with a hyperope or a myope. In the presence of much astigmatism, he is not even sure of this. I have seen a candidate for the Board take twenty minutes to get information that would have been revealed by a single flash with the retinoscope and then get it wrong. Even if the doctor does not value his time he introduces a source of error every time he wears down his patient. Patients should be relaxed and leisurely.

With the newer self-illuminating retinoscopes, observation through a closed pupil is an easy trick. Fortunately, young persons, whose accommodation is most troublesome, usually have large pupils. The results are by no means to be accepted as absolute, yet in about three quarters of the cases they are fairly reliable, and surprisingly often they give the exact sphere and cylinder of the final prescription.

Since speed is an object, an apparatus is helpful, permitting rapid changes of lenses, like a phoroptometer or Green's refractor. Dry retinoscopy may be accomplished in two ways. One is with the patient looking at distance; the other is with the patient looking at the retinoscope. One method may be used to corroborate the other.

NONCYCLOPLEGIC EXAMINATION

No excuse is needed for the teaching of expert noncycloplegic refraction. Not only is it in skilled hands often more potent than cycloplegia but it also is the best check on the action of cycloplegic drugs, which are sadly erratic. It is the only recourse when mydriasis is contraindicated. Many candidates suffer from the delusion that when cycloplegia fails, nothing else can work. Most of them never have learned how to perform competent "dry" refraction.

ASTIGMATIC DIALS

Leaving in the trial frame, unchanged, the highest plus sphere (or lowest minus sphere) found by dry retinoscopy should automatically provide the fogging sphere required for use with the astigmatic dials. This then is the moment to use this test. The common cause of failure with dials is inadequate fogging. Overfogging is also misleading. As retinoscopy is not entirely trustworthy, in order to determine whether the posterior plane of the conoid is exactly on the retina, a plus sphere may be added, which should increase the blur. The favored method is to expose the clock dial or sunburst of the Lancaster-Regan or the Verhoeff charts. With proper fogging, the most distinct line lies in the axis of the plus cylinder. Replacing the clock with the cross dial, the examiner places one cross line on this axis. Transverse to this is the blurred minus axis. This axis is cleared by concave cylinders, increased until the two crossed lines exactly balance.

There should now be some family resemblance between the result of the dial test and the result of dry retinoscopy. The retinoscopy is so temperamental that a surer check of the dial test is needed. Lancaster,[1] in his original paper in 1915, recommended confirming the axis by rotating the cylinder. This is an early instance of verified refraction. The power may then be tested by alternating equal cylinders before the trial case correction at opposite axes.

Read before the Section on Ophthalmology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

[1] Lancaster, W. B.: Subjective Tests for Astigmatism, Tr. Am. Acad. Ophth., 1915, p. 167.

CROSSED CYLINDERS

Now is a favorable time for the use of cross cylinders as a further check on astigmatism. With the same correction in the trial frame, the examiner tests the axis by flipping the cross cylinder with the handle held in the axis thus found. He then holds the axis of the cross cylinder in this axis and flips again. This tests the power.[2] A modification of the cross cylinder test is the "subtraction test"[3] I described years ago. If any two of these tests agree, the chances favor the result so obtained. The one giving the best visual acuity is usually the correction of choice.

SPHERICAL ERROR

The tests for astigmatism can be performed with only an approximate knowledge of the sphere, but the sphere cannot be determined accurately without the correct cylinder. This routine is now at the point where the cylinder has been determined and is set up in the trial frame. Nothing further is therefore needed to proceed with the fogging test. At present the approved method is to add plus spheres, making the eye artificially myopic. The blur resulting is then reduced by diminishing the plus overcorrection step by step. In response to increased blur by ciliary action, the eye is supposed to relax. Usually that is what happens, though not invariably. Usually greater relaxation takes place if both eyes are seeing and are unfogged simultaneously than when each eye is unfogged with the other covered. This often amounts to as much as 0.75 D. About twenty years ago Burdon-Cooper[4] reported to the English Speaking Congress on a series of cases in which binocular fogging was more potent than atropine. Shortly after this Dorland Smith[5] introduced what he called "cyclodamia." This is a binocular technic. It unfogs from complete blur. This is produced by adding more than + 1.50 to the spheres found by dry retinoscopy combined with the cylinders last determined. The method is distinguished by noting three levels of blur. The levels to be watched for: (1) when binocular vision is 6/60 (20/200)—the eyes are fogged by about + 1.50; (2) when the 6/12 (20/40) line is visible—the fogging is about + 0.50, and (3) when this + 0.50 is removed, the 6/6 (20/20) line should be read. This is not usually the lens affording clearest sight, but is a slightly higher correction. The fog is then almost lifted. This is the time to equalize the correction of the eyes. Usually the vision is equal when the fogging sphere over each eye is the same. If the sight in one eye is not as good as in the other, that eye is probably more heavily fogged. It should be unfogged until the vision is equal in both eyes. Therefore, as 6/6 (20/20) is seldom the patient's best acuity, vision is usually still slightly overcorrected on the plus side, so that the eyes are cleared a little at a time until the best vision is obtained. While Smith's levels are not as exact as this rule implies, they are about as reliable as any refraction tests.

NEAR POINT TEST

Both eyes at this point should have the same near point. This near point should also correspond to the age of the patient. The test is made without alteration of the lenses in the trial frame except that in presbyopia addition of a sphere is required to permit reading. These spheres should be equal in the two eyes and correspond to the age.

There are now three checks on the sphere: (1) the dry retinoscopy, (2) the cyclodamic levels and (3) the near point test. The different observations which should tally, if the examination so far is trustworthy, are:

1. The complaint and history
2. The visual acuity (including pinhole)
3. Preliminary retinoscopy (with variants)
4. Astigmatic dials
5. Cross cylinder test
6. Cyclodamia (three levels)
7. Near point test

If the sequence outlined is followed, it will be seen that the changes in lenses in the frame are reduced to the minimum.

1. The final sphere of the retinoscopy is also that used for the dial test.
2. The lenses left by the dial test are used unchanged for the cross cylinders.
3. The cylinders which result from the tests for astigmatism are not touched again, but carry through the fogging test.
4. For cyclodamia both sphere sides of the phoroptometer are rotated equally and reduced simultaneously. Notation is made of the three levels.
5. The acuity is then equalized.
6. The unfogging is completed.
7 The lenses so found are those used for the near point test.

The advantage of this method of simultaneous binocular fogging should be obvious. It is often three quarters of a diopter more effective than uniocular fogging, and it is the only method, either dry or cycloplegic, in which it is possible to handle both eyes at the same time, eliminating one test.

CYCLOPLEGIA

It is preferable to make routine use of cycloplegia in young persons with active accommodation. To be sure, a few oculists take the position that in the hands of seasoned examiners nothing can be accomplished with cycloplegics which cannot be as well or better effected without them. Even they are rather tolerant of the recommendation that novices should examine with cycloplegics. A recent study[6] found 16 per cent of patients showing 0.75 to 1.00 D. more hyperopia or less myopia with cycloplegia. This means that cycloplegic examination is sometimes more effective, just as at other times dry refraction gives more complete relaxation. Neither is as uniformly reliable as advocates like to believe.

Cycloplegics also tend to allay the tension engendered by emotional stress. This property is as useful as the effect on the accommodation, which is rather fallible. Unless contraindicated, as by a shallow anterior chamber, cycloplegia should be used on the chance that something of importance may be revealed. It is useful if only to confirm the noncycloplegic observation, when dry tests give inconsistent results.

Under cycloplegia, to avoid the customary "static refraction" with hit or miss changes of sphere, and if necessary also of cylinder, aimed at giving 6/6 (20/20) acuity, the routine followed is theoretically similar to that just outlined for dry refraction, cylinder first and then sphere, with best vision the criterion: (1) retinoscopy, (2) cycloplegic acceptance of cylinder with dial tests and cross cylinders, (3) choice of sphere at trial case and (4) near point test for residual accommodation.

These tests should confirm the precycloplegic tests. They should also be consistent with one another. If the cycloplegic tests for sphere and cylinder confirm the dry refraction, then the duplication is usually unnecessary.

Usually the cycloplegic tests will confirm the precycloplegic observations. Results can then be accepted for prescription of lenses. Because these methods of examination so often produce identical results, most ophthalmologists tend to omit one or the other and thereby lose the chance to check their results.

POSTCYCLOPLEGIC EXAMINATION

The use of cycloplegics may uncover some blunders in the dry tests. When they differ from the precycloplegic observations, a postcycloplegic examination is necessary. The cycloplegic tests alone cannot be relied on for two reasons. The dilated pupil exaggerates the aberrations of the eye. The cycloplegia is itself uncertain. Vision with the dilated pupil may not be quite as accurate. The postcycloplegic tests follow the precycloplegic routine. Contrary to custom, it is often advantageous to make the postcycloplegic examination before the cycloplegia is entirely worn off, so that asthenopic influences are in abeyance.

SUMMARY AND CONCLUSION

This paper is inspired by the limited knowledge of refraction exhibited by candidates for the Board examination. Even the candidates who obtain satisfactory results at the practical examinations show training confined to only one of the standard methods. Young assistants can usually operate on cataracts better than they can fit patients with glasses.

The paper presents a sequence which permits all tests to be checked by other technics, based on different principles. By following the order indicated few changes of lenses are needed, so that the routine is fast as well as accurate. It is useful for teaching and for occasional fitting of glasses by general practitioners. It is also well adapted to routine office refraction.

For clearness the details of the tests available in treatises on refraction have been omitted. So, also, are variants, such as choice of cycloplegics, refraction with plus cylinders instead of minus and cylinder retinoscopy, which do not materially affect the use of the routine described. In general, ophthalmologists use some approved method of refraction and trust to luck that it will give correct results. The results should be verified to enable one to be as certain as possible.

ABSTRACT OF DISCUSSION

Dr. M. Hayward Post Jr., St. Louis: Today the problem of the relation of the medical profession to the art of refraction is one that is uppermost in the minds of all thinking ophthalmologists. It is only through complete understanding of the physiologic and pathologic processes of the complex organ of sight, and its close relationship to the body as a whole, that this examination can be properly carried out. It is only through our ability to give the highest grade of service, thereby achieving the finest results, that we may hope to retain the confidence of the public. Dr. Beach has pointed out the simple obvious facts, but I regret to say that the lesson to be learned therefrom, in my experience in conducting the examination of students of all ages, has, as a rule, not been put into practice. This is all too often true, not only of the young and inexperienced, but even more so of the older and busier practitioner. The fundamental difficulty lies in the graduate training in the eye departments of the medical schools. Here great stress is laid, as it should be, on retinoscopy under a cycloplegic. The mentality, and frequently a language difficulty, often make this type of examination a necessity in clinical work. But in private practice, where the grade of intelligence is higher, and the time of the average patient more valuable, such a procedure in all cases is neither practicable nor desirable. Here the art of "dry refraction" becomes of vastly greater importance, and many young ophthalmologists, fresh from clinical training, are at a loss as to the proper procedures. One aspect of this tendency toward onesidedness may be gleaned from the setup in many of the largest clinics, where the use of the astigmatic dial is, apparently, a lost art. This is harmful. At least as a check-up on other methods of refraction it is of the greatest value, and, indeed, in the hands of experts gives a rapid and exact method of estimating astigmatism, especially when combined with the use of the crossed cylinder. The older ophthalmologist often falls into a rut and, from lack of time and greater interest in the more spectacular aspects of surgery and pathology, fails to "verify" his refraction. The result is that the majority of older ophthalmologists are notably poor refractionists. The teaching of refraction should not be left solely in the hands of the residents and younger members of the staff, but it should be carefully and conscientiously supervised and controlled by the more experienced of the faculty.

Dr. Hugo L. Bair, Rochester, Minn.: Refraction has two correlated aspects: one is the precise optical examination of the eyes and the other is to provide comfortable vision which is satisfactory for the patient's requirements. Dr. Beach's excellent paper stresses the first aspect. He includes the history as a part of the procedure. This is extremely important with regard to the second aspect of the refraction. The examiner should decide, if possible, whether or not the chief complaint is likely to be related to use of the eyes and whether or not any refractive error or imbalance of the ocular muscles could be the basis for it. This decision is significant in the determination of the final prescription. It is also important to know what vocational and avocational demands are made on the patient's eyes. Dr. Beach mentions retinoscopy as the preliminary step in determination of the refractive error. Too often, in the teaching of refraction, either insufficient emphasis or wrong emphasis has been placed on retinoscopy. It can be more than simply a rough guide to the degree and type of refractive error. In Dr. Beach's system of refraction retinoscopy assumes a place along with other procedures. The findings on retinoscopy should be checked by, and should also be a check on, the procedures. It is as valuable in cyclodynamic as in cycloplegic refraction. In case of a normal pupil and no cycloplegia, retinoscopy should be done by fogging; the more hypermetropic meridian should be slightly overcorrected on the plus side with a sphere. The sphere is left in place in the trial frame and a minus cylinder then is used to determine the astigmatism. If the combination thus found is left in place, it can be used as an immediate basis for the subjective refraction. An important principle that is not sufficiently emphasized in the teaching of refraction is the production of rapid contrasts to determine the best correction. Use of the cross cylinder brings this out very well in the determination of astigmatism, but the same principle is applicable to the determination of the spherical correction for the single eye as well as in the comparison of the corrections in the two eyes. In determination of the spherical correction for the single eye, a small plus and an equally small minus sphere are quickly interchanged in front of the eye and the correction in the trial frame is varied until the same degree of blur is produced with each of the check lenses. Rapid interchange does not allow time for the small minus sphere to be overcome by accommodation.

Dr. Joseph I. Pascal, New York: Dr. Beach mentioned the use of the cross cylinder in connection with the line charts. It cannot be emphasized too strongly that these two methods of examination differ radically in the method of application. It has been shown, and can be shown by the study of the retinal images and also mathematically, that a cross cylinder works best only when the eye is not fogged, that is, when the eye is in a condition which may be called meridional balance. In this condition the astigmatism has been changed to mixed astigmatism, whereas the line charts work best only when the eye is fogged, slightly fogged or half fogged. With reference to refraction in general, Dr. Beach has well shown that there is need of having more than one method at one's command, but there is one point in this connection which needs to be mentioned, that is, different methods of examination will frequently give slightly different results, occasionally decidedly different results. The most plausible explanation for this observation is that the different zones in the pupil generally have somewhat different refractive errors; for example, with a 4 to 5 mm. pupil, if one isolates a 2 mm. zone in the lower part of the pupil, one often finds a different refractive condition from what one would find in a 2 mm. zone situated at some other part of the pupil. When one examines the eye with the pupil exposed as a whole, the result is really an average of different refractive conditions of the different pupillary zones. When these different zones are decidedly different in their refractive errors, the same average can be obtained by a combination of different elements, so that there may be different observations, two or three of which will give practically the same visual acuity. In such cases, which are rather puzzling, I would like to ask Dr. Beach what he suggests doing. I myself have always suggested trying the different prescriptions at the near point to see which gives the best results there, because, as the pupil contracts, there are fewer zones which have to be averaged, and that correction which will best suit the eye for both far and near will be obtained. Incidentally, an understanding of this point of variability in the pupillary zones is valuable in studying and evaluating the relative validity of different methods of refraction.

Dr. I. S. Tassman, Philadelphia: Dr. Beach has presented a thorough procedure for refraction. However, nothing has been said about refraction for children. It ought to be emphasized that cycloplegic refraction with atropine should be employed with children up to the age of at least 12 years. The preliminary examination should be carried out as Dr. Beach described, then followed by cycloplegic examination and also a postcycloplegic examination. All of the methods and tests that are mentioned and described can be applied in every case, as Dr. Beach pointed out, with one checking the other. The power of discrimination ot the patient should also be evaluated by the examiner. It is important that one recognize the visual as well as the mental alertness of the patient is important, and that should be taken into consideration in determining the best result obtained in that particular patient.

Dr. S. Judd Beach: Cyclodamia is the name that Dorland Smith gave to a binocular form of descending fogging. The vision is deeply fogged by high convex lenses. Both eyes are exposed at the same time. Three levels of visual acuity are noted as the fog is gradually reduced. At the top level the 20/200 line becomes visible binocularly. This indicates fogging by a + 1.50 sphere in both eyes; at the second level the 20/40 line appears, indicating fogging by + 0.50 spheres; at the lowest level, the 20/20 line is seen. In obtaining the cycloplegic acceptance, textbooks tell one to change spheres, a little plus or a little minus, until 20/20 vision is reached. If in this way 20/20 vision is not obtained, then cylinders should be tried. On the contrary, I feel that the routine I described for noncycloplegic refraction is also best under cycloplegia. First the cylinder and then the sphere should be determined. I was not prepared to have so many persons agree with me. What Dr. Bair added to the discussion about the near point test is true, but, as Dr. Post said, that does not make it any the less desirable to measure the near point in each case. Dr. Pascal raised a significant question concerning the variation in refraction in different areas of the cornea. There is some question as to whether, with the enlarged pupil, the patient averages these different refractive errors or whether, as Dr. Crisp and Dr. Lancaster some time ago suggested, the patient chooses the area he prefers or with which he sees best. I cannot go into that, because it would take a long discussion to explain the optical principles involved, but there are two points of view with regard to that. Of course, Dr. Tassman's contribution about the examination of children is important.

Clinical Notes, Suggestions and New Instruments

"DIASONE" THERAPY OF ACTINOMYCOSIS OF THE JAW

Report of a Case

HARRY L. ARNOLD Jr., M.D.
and
E. R. AUSTIN, M.D.
Honolulu, Territory of Hawaii

In March of this year (1948) Dr. Fernando Latapí of Mexico City demonstrated to one of us (H. L. A.) a case of actinomycosis in which an extensive cutaneous granuloma was healing rapidly, apparently as a result of the oral administration of disodium formaldehyde sulfoxylate diaminodiphenylsulfone ("diasone," Abbott). A similar response had been observed by him in two previously treated patients with this disease. The dose employed was that customarily used in the treatment of leprosy in Mexico: 15 grains (1 Gm.) daily for the first week, 20 grains (1.3 Gm.) daily for the second week and 25 grains (1.6 Gm.) daily thereafter. This is a much larger initial dose than that used in Hawaii (5 grains [0.3 Gm.] a day, three days a week, raised in 5 grain [0.3 Gm.] increments, on those days only, till 25 grains [1.3 Gm.] is reached, and then the same initial dose and the same increments on the alternate days). It is three times as large as the initial dose recommended by the Fifth International (Havana) Leprosy Congress in April of this year. Extensive experience in Guadalajara and in Mexico City indicates, however, that it is not dangerously high.

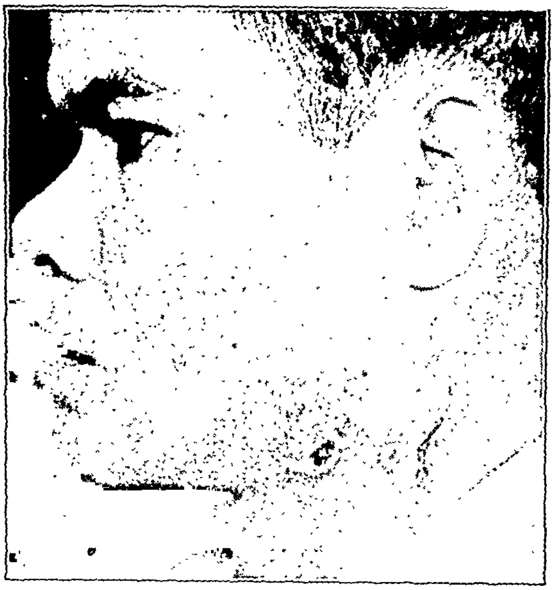

Fig. 1.—Lesion on July 3, before treatment.

The purpose of this report is to bring these cases, and an additional case of our own, to the attention of American physicians.

REPORT OF A CASE

E. D., a 40 year old Filipino milker of cows, was first seen by one of us (E. R. A.) on July 9, 1948, because of swelling of the soft tissues immediately behind the left ramus of the jaw (fig. 1) following extraction of a tooth about two months previously. Treatment by another physician, consisting of twelve intramuscular injections of penicillin, had had no effect, the mass having increased steadily in size. The patient's temperature was 99.6 F. Roentgenograms showed irregular decalcification of the left side of the mandible; the bony cortex was intact, however, and the process was interpreted by the roentgenologist as secondary to the soft tissue mass. Kolmer, Wassermann and Eagle reactions of the blood were negative.

From The Clinic, Honolulu.

A biopsy of the mass revealed only vascular granulation tissue with suppuration. A second biopsy specimen, from inside the mouth, showed a similar process, in which some amorphous material was found which suggested a fungus colony. Further sections, however, failed to confirm this observation and showed changes which were interpreted as indicative of a mixed tumor of the parotid, with nonspecific infection in the region of the extraction of the tooth.

The patient received penicillin in oil and wax intramuscularly, 300,000 units on June 14, 150,000 units on June 22 and 300,000 units on June 25 and 29 and on July 2. On July 3 the lesion had begun to drain thick pus from several orifices, and the patient was hospitalized and given 600,000 units of penicillin in oil and wax intramuscularly daily until July 9, at which time slight improvement had occurred, all of the external discharge of pus having stopped. On July 12 another biopsy specimen from inside the mouth revealed only nonspecific pyogenic vascular granulation tissue.

On July 12, two fluctuant areas on the surface of the mass, which was at this time approximately 8 cm. in diameter, were deeply incised, and the evacuated pus collected in a Petri dish and examined. Several yellow granules were observed, which proved microscopically to be colonies of Actinomyces.

Weekly Blood Cell Counts and Urinary Albumin Determinations During Administration of "Diasone"

* Percentage of total.

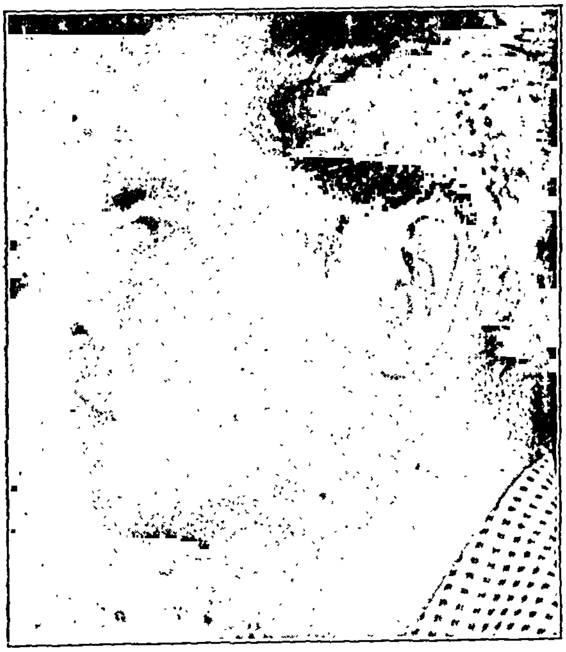

Fig. 2.—Lesion on August 10, at the end of the fourth week of "diasone" therapy.

"Diasone" therapy was begun immediately in a dose of 15 grains (1 Gm.) daily, and the dose was increased each week by 5 grains (0.3 Gm.) daily No intolerance was reported by the patient. The blood cell counts are shown in the accompanying table. At the end of the first week, both the incisions had healed completely; at the end of the second week, the lesion was still very firm, but the surrounding soft tissue swelling was noticeably diminished; at the end of the third week, the lesion was reduced to about two thirds of its original size and the skin was freely movable over it; at the end of the fourth week (fig. 2) there was only a residual fibrotic nodule, less than one-sixth the size of the original mass, with normal overlying skin except for a few scars. The red cell count had risen to nearly 5,000,000 and the hemoglobin to 16 Gm.

COMMENT

The response to penicillin in the hospital is in line with previous reports of the effectiveness of this drug in actinomycosis, and suggests that—had the diagnosis been known at that time, so that more confidence could have been reposed in this form of treatment and the dose increased or the schedule prolonged—a cure might have been obtained in this way. However, the decided flare-up of the process after the penicillin therapy was stopped, seems to exclude any possibility that this drug participated in the subsequent improvement of the lesion. This improvement began so promptly and progressed so rapidly under "diasone" therapy that it seems reasonable to attribute it to the latter drug.

The initial drop in the red blood cell count may have been due to the hemolytic effect which "diasone" is known to have in certain patients. The prompt return of the cell count to normal without adjuvant therapy of any sort indicates that this effect may be a transitory one.

CONCLUSIONS

Biopsy may be a less satisfactory means of diagnosis in actinomycosis, probably because it is often of necessity relatively superficial, than examination of the purulent discharge for "sulfur granules."

"Diasone" seems worthy of further trial in the treatment of actinomycosis.

881 South Hotel Street.

SUBACUTE BACTERIAL ENDOCARDITIS

Report of a Case of Reinfection

MARVIN J. ROSENBURG, M.D.
Los Angeles

The treatment of subacute bacterial endocarditis has been divided historically by most authors into three distinct periods of time. The first encompasses the period before the use of sulfonamide drugs, when it was estimated that the incidence of spontaneous recovery varied between 0 and 1 per cent. The second phase began with the use of sulfonamide drugs, either with or without fever therapy. Lichtman,[1] in an analysis of 704 cases falling in this group, computed the incidence of recovery to vary between 4 and 6 per cent. This was felt to represent a significant percentage increase. Since the advent of penicillin therapy, in the third period, a considerable number of authors have discussed the principles of treatment, the dosages used and the results obtained with penicillin. The percentage of cured patients has increased until it now is estimated to lie between 60 and 80 per cent. Some of the cases have been followed up for as long as thirty-five months after treatment

---

From the Department of Medicine, Wadsworth General Hospital, Veterans Administration Center, Los Angeles.

Dr. Morley J. Kert, Junior Consultant, Internal Medicine, Wadsworth General Hospital, gave helpful suggestions and criticisms during the preparation of this paper.

[1] Lichtman, S. S.: Treatment of Subacute Bacterial Endocarditis: Current Results, Ann. Int. Med. 19: 787 (Nov.) 1943.

was concluded.[2] Hunter cited 41 cases of clinical cure, some of which were followed-up for eighteen months after treatment,[3] while Priest, Smith and McGee [4] stated that thirty-five months had elapsed since the treatment in some of their cases.

The purpose of this paper is to report a case of subacute bacterial endocarditis which recurred twenty months after completion of the first course of therapy. The apparent adequacy of the primary treatment, together with the long interval during which the patient was symptom free, make it seem that reinfection, rather than relapse had occurred.

REPORT OF A CASE

First Admission.—A 31 year old white salesman was admitted April 8, 1946, to a hospital, complaining of fatigue and chronic low grade fever of two months' duration. Approximately two months before entry he had had a mild infection of the upper part of the respiratory tract characterized by persistent low grade fever, fatigue, loss of energy and transitory arthralgia of the knees, elbows and back. He took sulfadiazine tablets for three days without relief. Immediately prior to entry, the right calf became painful, tender and swollen and two small red painful nodules appeared on his fingers. Physical examination revealed a well nourished normally developed white man who was not acutely ill. There was a reddish nodule on the palmar surface of the right hand. He had a ticktack rhythm of the heart, a split mitral first sound, but no murmurs were heard. The right calf was exquisitely tender and was ¾ inch (2 cm.) larger in circumference than the left.

Laboratory examination revealed mild anemia, leukocytosis and an elevated sedimentation rate. Two blood cultures were positive for Streptococcus viridans. While the patient was in the hospital cutaneous lesions suggestive of erythema nodosum developed, with petechial lesions of the uvula and electrocardiographic changes suggestive of rheumatic fever. Three weeks after entry an aortic systolic and diastolic murmur appeared, together with a widened pulse pressure. A diagnosis of subacute bacterial endocarditis, presumably on a bicuspid aortic valve, was made. The patient was treated with 800,000 units of penicillin daily for six weeks. After three negative monthly blood cultures and an asymptomatic follow-up period he was discharged as cured.

Second Admission.—The patient remained well until he entered the reporting institution on Feb. 11, 1948, because of a three week history of low back pain. This was deep to the right posterior iliac aspect of the spine. His temperature was noted to be 101 F. rectally. Before entry, while under "pentothal sodium" (sodium 5-ethyl-5-[1-methylbutyl] thiobarbiturate) anesthesia he had received osteopathic manipulation of his back. Exacerbation of his low back pain had resulted. He was also given penicillin therapy during this period, and of interest is the fact that his temperature returned to normal, only to rise when the penicillin therapy was discontinued.

On examination he was seen to be well developed and nourished, but immobilized in bed by his severe low back pain. Positive physical observations were of a slight left-sided cardiac enlargement, a forceful apical beat, an aortic systolic grade 1 murmur, which was transmitted to the neck, and a grade 3 diastolic aortic murmur. This was transmitted to the apex. His blood pressure was 150 systolic and 70 diastolic. The orthopedic consultant observed no local pathologic condition in the back, but did feel that any torsion of the spine aggravated the pain.

Laboratory examination revealed 12,660 white blood cells, with a normal differential count, and 4,100,000 red blood cells, with 86 per cent hemoglobin. The sedimentation rate was 28 mm. in sixty minutes. Four successive blood cultures were positive for S. viridans. The urine, Wassermann reaction of the blood and spinal fluid were normal. Roentgenograms of the back revealed narrowing of the lumbosacral segment with apparent calcification of the nucleus pulposus. There were minimal arthritic changes of the apophyseal joints. There was minimal enlargement of the left ventricular outflow tract shown in roentgenologic examination. An apical abscess of the lower right first molar was found, and culture of the abscess fluid after extraction yielded S. viridans.

The organism isolated by blood culture proved to be sensitive to less than 0.1 unit of penicillin per cubic centimeter by in vitro tests. Patient was given 6,000,000 units of penicillin daily, with return of the elevated temperature to normal within three days. The penicillin was given by intramuscular injection each two hours. After twelve days the dosage was decreased to 3,000,000 units daily. This was continued for twenty days, with a serum penicillin level of 5 units per hundred cubic centimeters. The total penicillin administered was 132,000,000 units in thirty-five days. The blood cultures, temperature and leukocyte count returned to normal shortly after specific therapy was begun and continued at normal levels for the succeeding five months. The sedimentation rate, at the time of writing, had been persistently elevated.

COMMENT

This case presents certain points of particular interest. I feel that the presence of an apical root abscess yielding the same organism as that seen on blood culture indicates the origin of the present valvular infection. This correlates with the work of Okell and Elliot,[5] who observed that 61 per cent of 84 patients experienced transient bacteremia following tooth extraction under general anesthesia. If pronounced gum disease was present, the figure rose to 75 per cent. Of interest is the fact that 12 of the 100 patients cited by these authors had bacteremia before any operative procedure had been done, indicating that transient bacteremia may occur at any time. Rhoads [6] obtained similar data by taking blood cultures at ten minute, three hour and twenty-four hour intervals after tooth extraction. Positive cultures were obtained in 8 of 25 cases. He also cited cases of patients with pronounced gingivitis who had positive blood cultures following the chewing of mint candies.[6] Correlation of this and other data has led most investigators to list the teeth and gums as the primary focus of infection in the majority of cases of bacterial endocarditis. This case is no exception.

It is not clearly established whether a previously inadequate course of penicillin therapy will alter the penicillin resistance of an organism to further treatment. The decided sensitivity of the organism in the aforementioned case raises the question whether this indicates a reinfection or a relapse. Several authors, among them Bloomfield and Halpern [7] and Flippen and his co-workers,[8] expressed the belief that inadequate courses of therapy, particularly if carried out for long periods of time, tend to increase the resistance of the organism to penicillin. Particularly would this be true if the second course were not given promptly after the relapse developed. The possibility that my patient might have a recurrent infection, therefore, further complicated the determination of how much penicillin to be given. Because of technical difficulties I was not able to secure an immediate report of the penicillin sensitivity of the organism. Consequently it was decided to begin with 6,000,000 units of penicillin per day. This was decreased when the penicillin sensitivity was obtained. The pronounced sensitivity displayed in this case, however, would seem to be corroborative evidence in favor of a reinfection.

Before determining that reinfection has occurred, one must first define what constitutes a cure. Goerner, Geiger and Blake [9] recognized this problem when they stated that spontaneous remissions might occur which may last for weeks.

Permanent disappearance of symptoms was rarely reported without specific treatment. A large number of patients have been reported to have become asymptomatic after being treated with small doses of penicillin, only to display a recurrence of symptoms when the penicillin therapy was discontinued. Because of this, it was felt that time was the only criterion of a permanent cure. Numerous authors have presented the same point of view.[10] Hunter stated that if relapses occur, they almost always develop in the first two weeks after therapy is stopped.[3] To avoid this, he advocated intensive therapy. Christie reported 147 patients treated under the English clinical trials committee and stated that when relapses occur they do so within thirty days after treatment and are extremely rare after fifty days. This principle was used to evaluate the efficacy of varied forms of treatment.[11] If their patients remained asymptomatic for fifty days after treatment, they were considered cured. There was relapse in only 1 of their cases after this time, with symptoms recurring sixty days after treatment. This was considered to be a reinfection, inasmuch as a different organism was obtained on relapse than had been seen on initial infection. Gefter and his co-workers [12] gave a slightly more conservative definition. They expressed the belief that twelve months should be considered the critical period. If a patient survives this period without a further development of symptoms, he is considered cured. Prior to the use of penicillin there were extremely few reports of patients living this long in remission. Therefore, if there is clinical or bacteriologic evidence of subacute bacterial endocarditis after this time, it is considered that the patient has a reinfection.

In view of the multitude of reports of clinical and bacteriologic cures of bacterial endocarditis which have appeared in the last few years, there are relatively few reported reinfections. Geiger treated 1 patient in whom the disease occurred six months after initial treatment,[13] and Paul and his co-workers [14] reported a case which they felt recurred seventeen months after the initial treatment course. Christie reported the aforementioned case. Cannady [15] treated a patient with reinfection occurring twelve months after the first attack. Thill and Meyer reported a patient who had a reinfection one year after treatment. He had been well and working until after a dental extraction clinical and bacteriologic evidence of reinfection was observed.[2c]

It is expected that cases of this type will become more frequent in the future. With the occurrence of an increasing number of cures of a previously uniformly fatal disease, the opportunity for reinfection will be heightened. Whether a valve additionally scarred following the eradication of a mycotic vegetation will be more susceptible to further infection than one scarred merely as a result of rheumatic fever or a congenital lesion is not at present known. It is felt, however, that the case presented herein is an illustration of a patient who was cured of his disease by means of penicillin and who experienced a reinfection at a later date.

It has been recommended that follow-up studies of all cured patients be done to forestall this possibility. Priest, Smith and McGee utilized weekly examinations of the white blood cells, sedimentation rate and blood cultures for the first month after treatment, semimonthly checks for the next six months and monthly examinations thereafter. Others have expressed the belief that the temperature and sedimentation rate are the most important observations. Jones and Tichy [16] reviewed the literature and found no active cases of endocarditis without an elevation of the temperature and sedimentation rate.

There are many variations of the aforementioned procedures which can be used. The primary point of importance would seem to be the use of one type of follow-up period to insure freedom from reinfection. This would be of most importance the first few months after treatment is concluded, but should also be done periodically thereafter.

SUMMARY AND CONCLUSIONS

A case of subacute bacterial endocarditis is presented which is believed to be an example of reinfection. Salient features of the case involving the portal of entry, sensitivity of the organism and response to treatment are outlined. A short discussion of the concept of reinfection in subacute bacterial endocarditis is presented. It is felt that one year should be selected as the dividing line between relapse and reinfection. Most cases will show a recurrence of symptoms in the first or second month after treatment is ended. It is believed that periodic follow-up studies should be done on all patients cured of subacute bacterial endocarditis.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report on the recommendation of its Consultants on Electroencephalography. The consultants are: Drs. Percival Bailey, Edward J. Baldes, Hallowell Davis and Frederic A. Gibbs.

HOWARD A. CARTER, *Secretary.*

TENTATIVE MINIMUM REQUIREMENTS FOR ACCEPTABLE DIRECT READING ELECTROENCEPHALOGRAPHS

The following requirements are based on recommendations drawn up by the American Electroencephalographic Society (1947). The recommendations of the Society were intended as recommendations to manufacturers, not as minimum requirements. In the following requirements it should be noted that certain items are specified herewith as minimum requirements for Council acceptance; others are stated as the recommendations of the American Electroencephalographic Society for desirable additional features for higher standards of performance.

A. NUMBER OF CHANNELS

Portable equipment may include a minimum of two channels. Clinical laboratory equipment shall include not less than four channels. For research equipment an even larger number of channels is usually desirable.

B. ELECTRICAL AND MECHANICAL SPECIFICATIONS FOR EACH RECORDING CHANNEL

1. *Linearity of Response.*—The deflection appearing in the record shall be directly proportional to the voltage applied to the input of the apparatus to within 10 per cent (or ½ mm., whichever is larger) up to an amplitude of linear deflection not less than 1 cm. in each direction from the base line (i. e., 2 cm. over all).

2. *Amplification.*—(*a*) When the controls are set for maximum amplification an input voltage change of 5 microvolts ($5\mu v$) shall give a deflection of not less than 2 mm. This requirement in conjunction with section B1 implies a sensitivity at the highest gain setting of not less than 2.5 μv per millimeter.

(*b*) The ratio between the maximum deflection proportional to the input voltage and the minimum visible deflection shall be not less than 40 to 1. For example, if a 1 cm. deflection is obtained from 160 microvolts input the deflection for 4 microvolts input must be visible at the same gain setting.

(*c*) The total attenuation available shall be not less than 1,000 to 1. The American Electroencephalographic Society recommends that there should be two controls of amplification. The principal control should have increasing steps of not more than 100 per cent per step and should provide an over-all attenuation of at least 25 to 1. The second gain control should provide continuous adjustment for equalization of the gain in the various channels.

3. *Frequency Response.*—(*a*) The over-all frequency response of the system shall be such that between 1 and 60 cycles per second the deflections at all frequencies shall be within 10 per cent of the average of the maximum and the minimum deflections within this range.

(*b*) Over-all time constant (R. C.), without low frequency cut-off filters, should not be less than 0.2 second. This implies a square wave response which declines to 0.37 of its peak value in 0.2 second.

(*c*) The American Electroencephalographic Society recommends the provision of both low frequency cutoff filters and high frequency cutoff filters.

(*d*) The American Electroencephalographic Society recommends that there should be no significant distorting resonance in the system outside of the frequency range of 1 to 60 cycles per second.

4. *Coupling of Controls.*—The American Electroencephalographic Society recommends that the operation of any one control should not alter the effective setting of any other control by more than 15 per cent.

5. *Noise Level.*—With the input short-circuited and with the controls set to meet the requirement of section 3 (*a*) no deflections greater than that produced by an input voltage of 2 micovolts (peak to peak) shall appear oftener than once a second on the average.

6. *Effect of Line Voltage Fluctuations.*—A line voltage fluctuation amounting to 5 per cent above or below the voltage recommended by the manufacturer as normal operating voltage shall not produce a deflection in the record greater than that produced by an input voltage of 2 microvolts (peak to peak).

7. *Discrimination.*—"Discrimination" here refers to the ratio of a potential difference applied between ground and the input terminals connected together (for a given deflection) to the potential difference applied between the input terminals for the same deflection. The discrimination of the instrument shall be at least 1,000 to 1. The American Electroencephalographic Society recommends even more discrimination, particularly in portable apparatus.

8. *Limitation of Arc Distortion.*—The maximum arc distortion shall be not more than that produced by a pen 10 cm. long.

C. Relationships Between Channels

1. *Coupling Between Channels.*—When the controls in all channels are set for equal sensitivity a potential difference applied to the input of one channel only shall not produce a deflection in any other channel greater than 1 per cent of that in the channel to which the potential difference is applied.

2. *Similarity of Channels.*—The American Electroencephalographic Society recommends that the several channels shall be as nearly identical as possible and suggests the following practical criterion: When all principal gain and filter controls are set to the same positions and the channels are matched for sensitivity by setting the appropriate fine controls and identical input signals are applied simultaneously to the inputs, then all of the channels should give records that are superimposable within 10 per cent or ½ mm., whichever is larger.

D. Recorder

1. *Recording Surface Travel.*—The recording surface shall travel from the operator's right to his left and shall be visible for a distance of not less than 60 cm. to the left of the recording line.

2. *Recording Surface Speed.*—The standard speed for recording shall be 30 mm. per second ±2 per cent. The American Electroencephalographic Society recommends that one faster and one slower speed (each at an integral ratio to the standard) be provided and that these speeds be selectable while the recorder is in operation.

3. *Recording Line.*—The width of the recorded line shall be not more than ½ mm. in all directions of travel.

4. *Spacing and Registration of Recording Lines.*—(*a*) At zero deflection all the recorder writing points shall lie within ±0.5 mm. of a line perpendicular to the time axis of the record in the plane of the record.

(*b*) The spacing between writing points at zero deflection shall be not less than the maximum peak to peak recordable deflection.

(*c*) The American Electroencephalographic Society recommends that the maximum spacing of the recorders shall be not more than 35 mm. It also recommends that unless satisfactory accuracy is guaranteed by the manufacturer each recorder should be adjustable (to the accuracy specified above) in respect to (1) registration in line with the other recorders, (2) lateral spacing between recorders and (3) pressure on the recording surface (accuracy not specified).

E. Construction and General Requirements

1. *Selector Switches.*—The American Electroencephalographic Society recommends that selector switches with at least 16 contacts should be provided at the input of each channel.

2. *Shielding and Grounding.*—The input leads from an appropriate distributor panel to the input selector switches shall be shielded and the shield(s) shall be securely attached to the common ground. Leads for the AC power supply shall also be shielded and the shield securely attached to the common ground.

3. *Electrode Connectors.*—The American Electroencephalographic Society recommends that input leads to connect the electrodes to the distributor panel should be provided and should be fitted with appropriate clips and plugs to suit individual requirements.

4. *Calibrator.*—(*a*) A calibrating circuit shall be provided at the input of the amplifiers. This circuit shall provide an input voltage of rectangular wave form in single pulses with an accuracy (including any transients) of ±5 per cent of the indicated voltage(s).

(*b*) The American Electroencephalographic Society recommends the following values for the indicated voltages of the calibrator: 5, 10, 20, 50, 100, 200, 500, 1,000 V.

5. *Meters.*—The American Electroencephalographic Society recommends that suitable meters or suitable test points for connecting meters should be provided to measure (*a*) the voltage of the calibration battery, (*b*) the voltage of all A and B batteries used in the amplifiers, and (*c*) the resistance or impedance of any two electrodes attached to the patient. A polarity reversing switch should be provided to make it possible to check the effect of electrode polarization on measurements of resistance.

6. *Noise and Vibration.*—The construction of the apparatus shall be such that no external insulation from mechanical vibration or from noise within the apparatus is required to prevent damage or to avoid spurious deflections in the record. The American Electroencephalographic Society recommends that the noise and vibration should be such that its effect on the patient will be negligible.

7. *Finish.*—All exposed surfaces should be resistant to the action of sodium chloride solution and to any recording fluids that are recommended by the manufacturer.

8. *Labels.*—(*a*) The electroencephalograph shall have a name plate giving the manufacturer's name, the serial number, the voltage and frequency (or frequencies) of the power supply and the power consumed by the electroencephalograph.

(*b*) All test points, dials, switches, etc., shall be clearly and appropriately labeled.

(*c*) The American Electroencephalographic Society recommends that a pilot light be provided to indicate when any power supply is switched on.

9. *Continuity of Operation.*—(*a*) The requirements specified in sections B1, 2, 3, 4, 5, 6 and 7 shall be attained within fifteen minutes of switching on and shall be maintained for a period of 24 hours of continuous operation.

(*b*) One hour of continuous recording at a speed of 30 mm. per second shall be possible without replacement of recording materials.

10. *Life.*—The requirements specified in sections B1, 2, 3, 4, 5, 6 and 7 shall be guaranteed by the manufacturer for a period of 1,000 hours' use or one year from date of shipment, which-

ever is less, exclusive of battery replacements or recharging and of tubes which may be guaranteed by their manufacturer.

11. *Safety.*—The apparatus shall conform in all respects to the recommendations of the Underwriters' Laboratory regarding the safety of the patient and the operator and also regarding fire hazard. There shall be no direct current coupling between the input grids of an amplifier and the patient. There should be no possibility of high voltage reaching the electrodes attached to the patient.

12. *Portable Apparatus.*—(*a*) In portable apparatus each unit of the equipment should be limited to a weight not exceeding 40 pounds.

(*b*) The visibility of the record need not meet the requirements of specification D1. Otherwise portable equipment shall fulfil the requirements of construction, performance, life, etc., as listed.

F. Information and Instructions

Adequate instructions shall be provided for the proper care and upkeep of the instrument. The American Electroencephalographic Society recommends that a functional wiring diagram of the amplifier circuits together with appropriate service information be supplied with each apparatus. It is highly desirable that a complete wiring diagram with schedule of values be provided.

G. Marketing and Advertising

Rules of the Council on Physical Medicine shall be adhered to by manufacturers of acceptable electroencephalographs.

REPORT OF THE COUNCIL

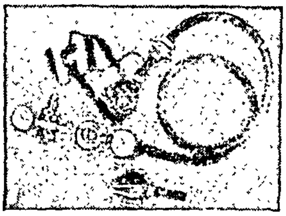
The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, *Secretary.*

M.S.A. PNEOPHORE ACCEPTABLE

Manufacturer: Mine Safety Appliances Company, Braddock, Thomas and Meade Streets, Pittsburgh 8.

The M.S.A. Pneophore is an apparatus for administering oxygen by intermittent positive pressure where breathing has been arrested or impaired. It consists of the following:

1. A high pressure reducing valve which reduces cylinder pressure to 3.4 atmospheres (2,600 mm. of mercury). A gage to indicate the oxygen cylinder pressure is part of this assembly.
2. A low pressure regulator equipped to reduce the pressure from 50 pounds per square inch to an adjustable pressure range from 0 to 30 centimeters of water (0 to 22 mm. of mercury).
3. A gage calibrated in centimeters of water to indicate the pressure being delivered.
4. A 6 foot (183 cm.) length of rubber tubing.
5. A differential pressure valve which converts a continuous positive pressure into an intermittent positive pressure, thus acting as an automatic respirator.
6. Two positive pressure face pieces, each with a 4 inch (10 cm.) length of tubing attached.



M.S.A. Pneophore

The apparatus is contained in a carrying case (optional) that is constructed of plywood and fiber with metal-reinforced corners and measures 41 by 30 by 20 cm. (16 by 12 by 8 inches). It weighs 3.7 Kg. (8½ pounds); the shipping weight is 5.4 Kg. (12 pounds).

After consideration of the available evidence the Council concluded that the apparatus is acceptable for use in medical institutions under the direction of a physician. It may be used in cases of respiration failure—e. g., poliomyelitis—for a short period of time (one hour or less) as emergency equipment under the direction of a physician. Because evidence at hand was not sufficient to establish its usefulness as an emergency respirator by fire departments and rescue squads or as a respirator for prolonged use in cases of infantile paralysis, it was not recommended for these purposes. With these reservations, the Council on Physical Medicine voted to include the M.S.A. Pneophore in its list of accepted devices.

Council on Foods and Nutrition

THE VITAMIN B COMPLEX

C. A. ELVEHJEM, Sc.D.
Madison, Wis.

This paper was prepared at the request of the Council and is one of a series appearing in The Journal. Later the entire series will appear in book form as the Council's Handbook of Nutrition. James R. Wilson, M.D., *Secretary.*

The group of dietary factors, the vitamin B complex, is included in the larger class of water-soluble vitamins because, like all vitamins, they are required by the body in small amounts and because the individual chemical compounds are soluble in water although the degree of solubility varies from the sparingly soluble riboflavin to the readily soluble choline. These are the main characteristics common to the individual vitamins because their functions in the living cell may differ greatly and their chemical structure may vary from the simple configuration of nicotinic acid to the more complex molecular structure of thiamine and riboflavin. The vitamin B complex is usually differentiated from the other water-soluble vitamins, such as vitamin C and related factors, on the basis of the source material used in early isolation work and the kind of experimental animals employed for the assay.

No attempt will be made to cover in this short summary the vast amount of literature which is accumulating on the water-soluble vitamins. A symposium entitled "The Vitamins,"[1] published by the American Medical Association in 1939, includes a survey of the facts known at that time. This chapter is a revised form of chapter 11 in the first "Handbook of Nutrition"[2] and will include only a general summary of the more significant facts, and reference will be made to original papers only when they have been published within the past few years. Since this review will stress the nutritional importance of these vitamins, the description of the clinical aspects of the deficiency diseases resulting from their deficiency will of necessity be limited. A recent publication by Jolliffe, Tisdall and Cannon[3] includes a description of the clinical symptoms.

The B complex now is known to consist of at least a dozen separate factors, ten of which can be obtained in crystalline form. Each factor will be discussed separately and in more or less chronologic order of its recognition and identification.

THIAMINE

Thiamine hydrochloride is a white crystalline substance readily soluuble in water, possessing a nutlike and salty taste and a yeastlike odor. The empiric formula is $C_{12}H_{18}N_4OSCl_2$, and the compound has the structural formula shown in figure 1.

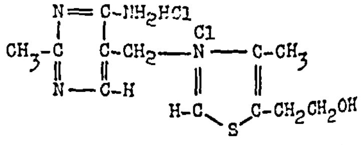


Fig. 1.—Structural formula of thiamine hydrochloride.

---

[1] The Vitamins, Chicago, American Medical Association, 1939.

[2] Handbook of Nutrition, Chicago, American Medical Association, 1943.

[3] Jolliffe, N.; Tisdall, F. F., and Cannon, P. R.: Handbook on Clinical Nutrition, to be published.

It is rapidly destroyed in neutral or alkaline solutions because of hydrolytic cleavage into its constituent pyrimidine and thiazole rings, but in acid solutions it can be sterilized for half an hour at 120 C. without appreciable loss of activity. In the dry form it is very stable and is not readily destroyed by oxidation. Its activity is rapidly destroyed by sulfite, a fact which may explain the loss of thiamine during the sulfuring of fruits. This vitamin also seems to be very rapidly destroyed in dehydrated meats and vegetables when the moisture content is approximately 5 per cent.

In foods and in tissues it occurs both in the free form and as thiamine pyrophosphate or cocarboxylase. In the latter form it functions in the living cell as a coenzyme in carbohydrate metabolism, especially in the metabolism of alpha-keto acids. In thiamine deficiency the utilization of carbohydrate is incomplete and pyruvic acid accumulates in the tissues, a condition which is used in determining thiamine insufficiency. Many of the symptoms which have been observed in beriberi may be related to faulty carbohydrate metabolism, although it is still difficult to differentiate an uncomplicated thiamine deficiency from multiple deficiencies. Some of the nerve lesions which have been described in experimental animals suffering from polyneuritis are certainly related to a deficiency of riboflavin, but there is also good evidence that a lack of thiamine may directly cause neuropathy.

The variety of symptoms seen in human beings has been summarized by Williams and Spies,[4] Jolliffe[5] and Jolliffe and his co-workers.[3] Wilder[6] has pointed out that the type of symptoms produced depends to a considerable extent on the rate at which the deficiency develops, but in all cases the subjects become depressed, irritable, quarrelsome, uncooperative and fearful. A relationship between thiamine deficiency and cardiac function has been recognized for many years, and Blankenhorn and his co-workers[7] have recently suggested seven criteria for the diagnosis of "beriberi heart." Anemia of the hyperchromic type has also been described in a number of thiamine-deficient patients.

The Food and Nutrition Board of the National Research Council recommends 1.2 to 1.8 mg. as the daily thiamine allowance for the average adult man. The minimum daily requirement as established by the United States Food and Drug Administration is 1 mg. The requirement is increased in periods of active growth and during pregnancy and lactation. Pathologic conditions, such as fevers and hyperthyroidism, in which there is a general increased metabolism, also increase the requirement. The effect of external temperature on the thiamine requirement of experimental animals has been given considerable attention. Mills[8] originally reported that rats need twice as much thiamine per unit of food at 91 F. as at 65 F. However, in more recent work by Kline, Friedman and Nelson[9] in which suboptimal levels of thiamine were used, evidence was presented to show that as the environmental temperature is increased, the daily requirement for thiamine is decreased.

Diets rich in fat have a definite sparing action on the requirement of thiamine in both rats and dogs. This is undoubtedly because fat metabolism does not require cocarboxylase. The human diet may rarely undergo sufficient change in fat content to alter materially the thiamine requirement. Cahill,[10] studying the urinary excretion of thiamine in human subjects, could observe no increase when part of the carbohydrate was replaced by fat.

The two commonest methods in use today for the quantitative estimation of thiamine are the thiochrome method and the yeast fermentation method. The detailed procedures are given in *Biological Symposia.*[11] The rat assay procedure is still recognized as the official method and is described in the "Pharmacopeia of the United States," thirteenth revision.

TABLE 1.—*Vitamin Content of a Few Typical Foods*

Foods[*]	Thiamine[†]	Riboflavin[†]	Niacin[†]	Pantothenic Acid[†][‡]	Vitamin B6[†][‡]	Biotin[†][‡]	Folic Acid[†][‡]

[*] Edible portion.

[†] Values are given in milligrams per hundred grams.

[‡] Values for pantothenic acid, pyridoxine (vitamin B_6), biotin and folic acid are based on data from only a limited number of samples. Some of the values may be low because of incomplete liberation of the vitamin. This is especially true in the case of pantothenic acid. For example, Nielands and Strong[88] found 3 mg. in 100 Gm. of spinach after maximum liberation and only 0.7 mg. by the old method. Dried yeast was observed to contain 40 mg. and fresh eggs 5.0 mg.

In table 1 are presented figures for the vitamin content of a few typical foods. It is evident that only a few foods can be classified as rich sources of thiamine; they include peas, beans, oatmeal, whole wheat and enriched flour and bread, lean pork and peanuts. However, one must not overlook the staple foods, such as milk, vegetables and fruits, which may contribute appreciable amounts of thiamine in the diet although the amount per unit of weight is relatively low. It is well known that significant amounts of thiamine may be lost during the preparation of foods, because of the fact that the vitamin is readily soluble in water and easily destroyed by moist heat. Under normal conditions there is probably little destruction of thiamine in the digestive tract, although intestinal disturbance may seriously retard the absorption of this vitamin.

The possible availability of thiamine synthesized by the bacterial flora of the gastrointestinal tract must not be overlooked, although it appears that less thiamine is produced than some of the other B vitamins.[12] It is also important to mention that the ingestion of live yeasts may render thiamine consumed in other foods unavailable for human beings (Parsons, Williamson and Johnson[13]). Severe thiamine deficiency can be produced in mice by feeding pyrithiamine, the pyridine analogue of thiamine (Woolley and White[14]), but the deficiency can be overcome by administration of an excess amount of thiamine.

Recently a factor destructive of vitamin B_1 has been found in raw fish. Green, Carlson and Evans[15] observed a type of paralysis in foxes fed diets containing 20 per cent fresh carp and identified the condition as a thiamine avitaminosis analogous to Wernicke's disease. Further studies[16] on the mechanism of inactivation point to an enzymatic destruction. Nonenzymatic thiamine-destroying factors have been found in seeds and in fern (Pteris aquilina) by Weswig, Freed and Haag.[17]

RIBOFLAVIN

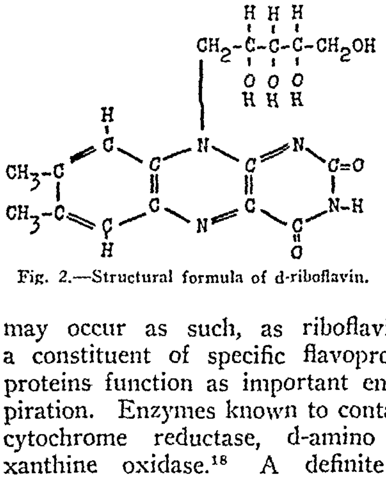

Fig. 2.—Structural formula of d-riboflavin.

Riboflavin is a practically odorless orange-yellow crystalline compound, which in water solution shows a characteristic yellow-green fluorescence. The empiric formula is $C_{17}H_{20}N_4O_6$, with the structural formula as shown in figure 2.

This vitamin is rather heat stable, especially in acid mediums, but extremely labile when exposed to light. In nature riboflavin may occur as such, as riboflavin phosphate or as a constituent of specific flavoproteins. These flavoproteins function as important enzymes in tissue respiration. Enzymes known to contain riboflavin include cytochrome reductase, d-amino acid oxidase and xanthine oxidase.[18] A definite reduction in the tissue concentration of the latter enzymes has been observed in riboflavin-deficient animals.[19] Aside from retarded growth in young animals, other symptoms include dermatitis and cataract in rats and characteristic paralysis in chicks. Work by Baum, Michaelree and Brown[20] indicates that the incidence of cataract in rats is increased if the diet supplies a small amount (1 to 2 micrograms daily) of riboflavin. Phillips and Engel have shown a specific neuropathologic condition of the main peripheral nerve trunks in chicks on low riboflavin rations. Similar changes were not observed in the rat until the riboflavin deficiency was aggravated by an increased fat content of the diet.[21] Both acute and chronic riboflavin deficiency has been studied in dogs.[22] On a diet very low in this vitamin a characteristic collapse syndrome and sudden death are observed in six to eight weeks. Prolonged subsistence on a diet low in riboflavin leads to neurologic abnormalities accompanied with myelin degeneration of peripheral nerves and the posterior columns of the spinal cord. Street, Cowgill and Zimmerman[22] have shown that opacities of the cornea may occur in the dog as well as in the rat.

Severe riboflavin deficiency has been produced in the monkey with no evidence of corneal changes.[23] The symptoms include lack of growth, dermatitis and anemia. Warkany and Schraffenberger[24] have described congenital defects and malformations of the skeleton of rats due to a low intake of riboflavin during the gestation period.

In human beings the symptoms include inflammation of the lips, fissures at the corners of the mouth, glossitis, dermatitis and vascularizing keratitis.[25] The ocular symptoms first described by Sydenstricker and his co-workers[26] appear to be constant and may appear *before other symptoms of the deficiency.* There is still considerable difficulty in distinguishing the glossitis or riboflavin deficiency from that of pellagra, pernicious anemia or iron deficiency and in distinguishing ocular ariboflavinosis from other conditions involving corneal vascularization.

The riboflavin content of foods may be determined by measuring the growth response obtained in chicks or rats maintained on basal rations low in the vitamin, but the more rapid microbiologic method of Snell and Strong[27] is now used extensively. Chemical methods involving measurement of fluorescence are also being used.[28] Riboflavin is widely distributed in plant and animal materials. *Liver, milk and green leafy vegetables* may be considered the best and most reliable sources in the human dietary. Seeds, which are so important as a source of thiamine, are poor sources of riboflavin.

The Food and Nutrition Board recommends 1.8 mg. of riboflavin as the daily allowance for men, and the Food and Drug Administration has accepted 2 mg. a day as the minimum daily requirement. The limited values in table 1 show that one serving of liver will adequately meet the daily allowance, that 1 quart of milk will supply the minimum requirement and that one serving of cheese or eggs will supply one fourth of the daily requirement. There is also considerable evidence for the bacterial synthesis of riboflavin in the intestinal tract and that some of this riboflavin can be utilized. Mannering and his co-workers[29] observed that with suboptimal intakes of riboflavin rats receiving a diet high in dextrin or starch grew better than those receiving sucrose-containing diets. When the diet was high in lactose the riboflavin excretion in the feces was many times the dietary intake. Denko and his co-workers[12b] observed the fecal excretion in human subjects to be three times greater than the intake during periods in which there was a low riboflavin intake. Hathaway and Lobb[30] observed a greater excretion when their subjects consumed natural foodstuffs than when they received purified diets, although the intake was the same. Sure and Dichek[31] have demonstrated, in the case of rats, that riboflavin has a pronounced beneficial effect on the economy of food utilization for the synthesis of body tissues. In this connection it is interesting to note that Murlin and his co-workers[32] reported that the biologic value of proteins in bread is improved in the presence of extra B vitamins.

NICOTINIC ACID

Nicotinic acid occurs as white needle-like crystals, is nonhygroscopic and stable in air and has the empiric formula $C_6H_5O_2N$. The structural formula of both the acid and the physiologically active amide are shown (*fig.* 3).

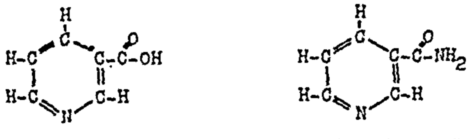

Fig. 3.—Structural formula of nicotinic acid (niacin) (left) and nicotinic acid amide (niacin amide) (right).

The sensation of flushing and erythema of the skin which is often observed on administration of nicotinic acid is not produced by nicotinic acid amide. Nicotinic acid is a comparatively weak acid, and its alkaline salts in solution show a slightly alkaline reaction. It is stable to autoclaving temperatures when in solution and shows no loss of activity when exposed to dry heat. Owing to numerous objections to the term nicotinic acid, niacin and niacin amide are used as synonyms for the acid and amide.

In the body nicotinic acid functions as a component of two important coenzymes, coenzyme I, or cozymase, and coenzyme II, which are concerned in both glycolysis and respiration.[33] The structure of the two coenzymes is similar, differing only in the number of phosphoric acid units. Coenzyme I is a diphosphopyridine nucleotide, and coenzyme II is a triphosphopyridine nucleotide. In nicotinic acid deficiency it is possible to demonstrate a decreased cozymase content of the liver and muscle tissue. There has been some question about the cozymase content of the blood during deficiency, but all workers[34] are now agreed that the change, if demonstrable, is very slight. It is thus impossible to use this method in the diagnosis of nicotinic acid deficiency.

The dog was used as the experimental animal in all of the early work on the antipellagra vitamin. Blacktongue in the dog was first described by Chittenden and Underhill, and in 1922 Goldberger and his co-workers concluded that blacktongue in dogs was analogous to pellagra in human beings. Through the use of highly purified rations supplemented with the newer B vitamins, it has been possible to demonstrate that the growing chick needs a dietary source of nicotinic acid for optimum growth and for the prevention of chick blacktongue.[35] In the rat niacin is an essential nutrient only when the tryptophan content of the diet is low.[36] The high incidence of pellagra, when the diet contains much corn, is undoubtedly due not only to the low amount of niacin in corn but to the fact that the main protein in corn, zein, is very low in tryptophan. A definite relationship between the niacin requirement and the protein part of the diet has been demonstrated in several different species, and it is apparent that the conversion of tryptophan to niacin is the most limited in the dog. An increased excretion of N′-methylnicotinamide on administration of tryptophan has been observed in rats[37] and in human beings.[38]

The early symptoms of pellagra are weakness, lassitude, anorexia and indigestion, followed by sore and ulcerated mouth and diarrhea. The typical dermatitis usually simplifies the diagnosis. A more detailed summary of the symptoms has been made by Harris[39] and by Youmans.[40] Spies, Walker and Woods[41] have shown that infants and children also suffer from nicotinic acid deficiency in areas where pellagra is endemic, although typical lesions are seldom seen in early infancy. Nicotinic acid is now widely used in the treatment of pellagra, but its use is most successful in conjunction with other vitamins and specific natural foods.

The activity of various compounds related in structure to nicotinic acid was investigated by Woolley and his co-workers,[42] and it was concluded that only those compounds which may undergo oxidation or hydrolytic conversion to nicotinic acid are active in the dog. Since that time some activity has been observed in human beings with quinolinic acid, pyrazine 2,3-dicarboxylic acid and pyrazine monocarboxylic acid. A paper by Dann, Kohn and Handler[43] summarized much of the work on these compounds, and from their results, as well as results in this laboratory, one may conclude that the activity of these compounds is greatly inferior to that of nicotinic acid.

Since nicotinic acid is not required by the rat unless there is an amino acid imbalance in the diet, the dog originally used by Goldberger and his co-workers for the assay of the antipellagra potency of foods is the only animal that has been used with any success. Fairly accurate values can be obtained by comparing the growth response obtained by feeding a definite weight of food with that obtained after giving a standard dose of nicotinic acid.[44] Chemical methods may be used on many foods, and an improved method has been described by Dann and Handler.[45] The most widely used method is the microbiologic method of Snell and Wright,[46] and this method gives reliable results when proper precautions are taken for the release of the vitamin in certain foods. The best sources of nicotinic acid include liver, yeast, lean meats and, to a lesser extent, peanuts, potatoes and vegetables.

It is difficult to establish an exact figure for the nicotinic acid requirement of human beings. Balance experiments are complicated by the fact that excess nicotinic acid ingested is excreted in several different forms. N′-methyl nicotinamide is the product which has received most attention.[47] Even when human subjects are given large doses of niacin, never more than 30 to 40 per cent of the dose can be accounted for.[48]

However, Knox and Grossman[49] have identified the corresponding 6-pyridone, which is an oxidation product, and this may account for much of the remainder. The niacin requirement is not only dependent on the dietary tryptophan but part of the niacin requirement may be satisfied through bacterial synthesis in the digestive tract (Ellinger and Benesch[50]). The Food and Nutrition Board has suggested 12 to 18 mg. as the daily allowance for an adult man, and the minimum requirement has been set at 10 mg. per day.

One may readily ascertain from table 1 why pellagra will develop with diets containing high percentage of corn meal and patent flour. These materials contain 1 to 1.5 mg. per 100 Gm., and one would have to consume 1,000 Gm. to meet the minimum requirement, which, of course, is impossible. In contrast to corn, wheat contains 5 to 7 mg. per 100 Gm. and would be a reliable source of nicotinic acid if 80 to 90 per cent were not removed during the milling process.[51] Whole oats are also low in nicotinic acid but barley is somewhat higher. One serving of liver will supply the daily allowance, and one serving of lean meat will supply over half of the daily requirement. Since nicotinic acid is a very stable compound, there is little destruction during cooking and the loss is negligible unless the cooking water is discarded. Although milk and eggs are low in niacin, these foods are important in the prevention of pellagra because they carry a good supply of tryptophan. Certain compounds may function as antagonists to niacin, for example, 3-acetyl pyridine, but these compounds apparently do not occur in nature in sufficient concentration to affect the niacin requirement.

VITAMIN B_6

The term "vitamin B_6" was first applied by György to a substance present in yeast which was active in the prevention and cure of a specific type of acrodynia in rats. A specific compound was subsequently isolated in pure form almost simultaneously (1938) in five different laboratories, and it was synthesized the following year by Harris and Folkers.[52] Pyridoxine hydrochloride is a white crystalline powder, slightly bitter in taste and odorless, and possesses the empiric formula $C_8H_{12}O_3NCl$.

In 1944 it was shown[53] that two derivatives of pyridoxine, namely, pyridoxal and pyridoxamine, were more active than the original compound for the growth of certain lactic acid bacteria. The three compounds have the structural formula shown in figure 4.

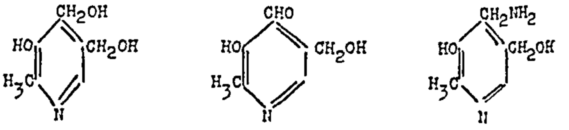

Fig. 4.—Structural formula (from left to right): pyridoxine, pyridoxal and pyridoxamine.

All three compounds are highly active in curing vitamin B_6 deficiencies in animals. All three forms occur in natural materials, although many tissues, particularly animal tissues, and yeast contain predominantly pyridoxal and pyridoxamine. Phosphorylated pyridoxal functions as a coenzyme for those enzymes which decarboxylate tyrosine, arginine, glutanic acid, "dopa," the precursor of melanin, and possibly other amino acids.[54] It also functions in reactions involving transamination[55] and tissues from pyridoxine deficient rats show a reduced amount of transaminase.[56] Pyridoxine is also closely related to tryptophan metabolism, since Lepkovsky and Nielsen[57] observed abnormal pigment in the urine of pyridoxine-deficient rats, and this was later identified as xanthurenic acid. Wood and Gunsalus[58] have shown that pyridoxal phosphate functions in the formation of tryptophan from indole and serine. There also appears to be a functional relation between unsaturated fatty acids and the vitamin.[59]

Pyridoxine has been shown to be essential in the nutrition of the rat,[60] the chick,[61] the dog[62] and the pig.[63] An acrodynia-like syndrome, characterized by edema, swelling and denuding of the paws and areas around the mouth and frequent thickening of the ears, is associated with pyridoxine deficiency in the rat,[64] although it has been demonstrated[65] that a lack of this vitamin may cause retarded growth without the dermatitis. The microcytic hypochromic anemia in dogs resulting from pyridoxine deficiency, reported by Fouts and his co-workers,[62] has been amply confirmed.[66]

No clearcut symptoms resulting from pyridoxine deficiency have been described in human beings. Spies, Bean and Ashe[67] have reported an additional improvement in pellagrins with pyridoxine therapy after treatment with nicotinic acid, riboflavin and thiamine. Smith and Martin[68] observed a rapid and satisfactory healing of the typical lesions of cheilitis with vitamin B_6 therapy. Although clinical treatment of such conditions as Parkinson's disease, muscular dystrophy and paralysis agitans has been studied, the results are not definite enough to permit postulation of the action of the vitamin or to associate any one of these syndromes with specific lack of pyridoxine in the diet. The human requirement is unknown, but animal experiments indicate that the vitamin B_6 requirement may be about the same as for thiamine, namely, about 1.5 mg. a day.

The most reliable method for determining the B_6 content of foods is probably the rat assay method,[65] although microbiologic methods involving Saccharomyces carlsbergensis and neurospora give values that are in reasonably good agreement with those obtained by rat assay.[69] Among the best sources are rice, bran, liver, yeast, cereals, legumes and milk. Whole wheat contains about 0.4 mg. in 100 Gm., most meats 0.4 to 0.8 mg. in 100 Gm. when fresh,[70] fresh vegetables about 0.2 mg. in 100 Gm. and milk about 1 mg. per quart (liter). Swaminathan[71] found diets consumed in India to supply 3.5 to 5 mg. a day.

PANTOTHENIC ACID

The member of the B complex which prevented dermatitis in chicks was first called the "filtrate factor." Although the so-called filtrate fractions prepared from liver extract were effective in the prevention of blacktongue in dogs, pellagra in human beings and dermatitis in chicks, it was demonstrated as soon as nicotinic acid was accepted as the antipellagra factor that the activity of these fractions in the prevention of chick dermatitis was not due to the nicotinic acid present but to a separate and distinct vitamin. Shortly thereafter, Woolley, Waisman and I[72] and Jukes[73] independently demonstrated that pantothenic acid, which Williams and his co-workers[74] had shown to be a growth factor for yeast as early as 1933, was similar to the chick antidermatitis factor. The complete synthesis of pantothenic acid was achieved in 1940.[75] The vitamin is now available as the dextrorotatory calcium salt, which occurs in fine dense white crystals that are odorless and slightly bitter in taste. The empiric formula is $(C_9H_{16}NO_5)_2Ca$. The structural formula for the free acid is shown in figure 5.

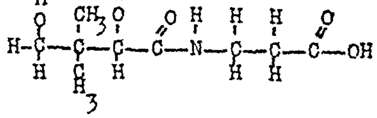

Fig. 5.—Structural formula for pantothenic acid.

Pantothenic acid is fairly stable when subjected to moist heat, especially at a neutral p_H, but is destroyed by prolonged dry heat. The compound is readily hydrolyzed into the two component parts in alkaline solution. The compound is widely distributed in nature, and recent work has shown that much of the vitamin may be present in bound forms. Lipmann and his co-workers[76] have shown that pantothenic acid is related to enzymatic acetylation. It was first shown[77] that a coenzyme was present in liver preparations which was necessary for the acetylation of aromatic amines. Later it was found[78] that the same coenzyme was needed for the acetylation of choline in brain tissue. This coenzyme was prepared in concentrated form and observed to contain about 10 per cent pantothenic acid. If pantothenic acid is related to all the biologic acetylations, it has a very important function. Riggs and Hegsted[79] have recently shown that acetylation of intraperitoneally administered p-aminobenzoic acid in rats was definitely reduced when the animals were given a diet deficient in pantothenic acid. The addition of the vitamin corrected the abnormality.

Rats placed on diets low in pantothenic acid grow very poorly, and in a few weeks necrosis of the adrenal cortex develops, which was first described by Daft and Sebrell.[80] Changes in hair pigmentation (graying) have been observed in many laboratories when black or piebald rats were used. Unna, Richards and Sampson[81] have published reproductions of photographs illustrating these fur changes in nutritional achromotrichia. Schaefer, McKibbin and I[82] have produced acute deficiencies of pantothenic acid in dogs that are characterized by sudden collapse associated with decreased blood dextrose, increased nonprotein nitrogen and lowered levels of blood chlorides. Severe intussusception in the intestinal tract and fatty livers have also been observed. Phillips and Engel[83] have reported specifi[illegible] changes of the spinal cord in chicks [illegible] ficiency of pantothenic acid. Wintrobe, Miller and Lisco[84] have also observed *neuropathologic changes in pigs on synthetic diets low* in pantothenic acid and other members of the B complex.

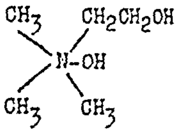
In spite of these interesting symptoms in experimental animals, little is known about the real significance of pantothenic acid in nutrition of human beings. Spies and his co-workers[85] concluded from studies based largely on values of pantothenic acid in the blood that pantothenic acid is essential to nutrition of human beings. Krahnke and Gordon[86] have studied the excretion of pantothenic acid in persons on different levels of intake. However, no specific symptoms in human beings have been correlated with a deficiency of the vitamin. This may be due to the fact that pantothenic acid is widely distributed and that even restricted diets may not be low enough to cause a serious deficiency.

No figures can be given for the daily human requirement. The relatively high amount of pantothenic acid needed to produce good growth in rats on synthetic diets has led to the assumption that the requirement is considerably higher than that of some of the other B vitamins. However, work in this laboratory indicates that the requirement for dogs can be satisfied with 0.10 mg. per hundred grams ration, a level similar to that of thiamine and riboflavin. According to these results, the human requirement cannot be above 5 mg. a day.

The pantothenic acid content of foods may be measured by growth experiments with chicks, but the microbiologic methods[87] are now in more general use. However, in order to obtain the total pantothenic acid in foods when microbiologic methods are used, it is necessary to treat the material with a liver enzyme and an intestinal phosphatase.[88] Liver is one of the richest natural sources, but meats, cereals and milk are also reliable sources. A few studies[89] have been made on the loss of pantothenic acid during cooking; there is, as one would expect, some loss, the retention varying from 60 to 100 per cent. Evidence is available to show that only about one half of the pantothenic acid in whole wheat is lost during the milling process.

CHOLINE

Choline is a colorless viscous fluid, and the more familiar choline chloride is a very hygroscopic white crystalline substance, with a salty bitter taste. The formula for choline is shown in figure 6. As expected from its chemical constitution, the compound is not stable to alkali treatment, but is stable to acids even at elevated temperatures.



$$(CH_3)_3N(OH)CH_2CH_2OH$$

Fig. 6.—Structural formula for choline.

Choline has been recognized for many years as a component part of the phospholipid lecithin, but its functional importance in nutrition was not apparent until Best demonstrated its role in the prevention of fatty livers in depancreatized dogs.[90] Choline is now considered an important member of the B complex, because most experimental animals, when placed on diets low in this compound and its precursors, show characteristic symptoms. The most obvious changes include the development of fatty livers and hemorrhagic renal lesions. The high requirement of the young rat for choline has been stressed by Griffith,[91] who reported fatty degeneration of the liver, renal lesions, ocular hemorrhages and regression of the thymus within ten days after the rats had been placed on a choline-low, but otherwise adequate, diet. When the deficiency persists in animals which have fatty deposits in the liver, cirrhosis will develop. In the early stages, this secondary change is also reversible if adequate choline is added to the diet.

The function of choline must therefore be related to the mobilization of fatty acids in the body. Experiments with the dog and the rat have demonstrated that neutral fat is involved, since fatty livers induced by feeding high cholesterol diets do not respond to choline therapy. The observations of du Vigneaud and his collaborators[92] that the methyl groups of choline, as well as those of methionine and betaine, are transferable in the animal organism has led to the postulation that one of the functions of choline is to supply labile methyl groups. McHenry[90] stated that there is evidence now that choline may function in at least three ways: to stimulate the formation of phospholipids, to make possible the production of acetyl choline or to supply labile methyl groups.

Extensive reviews have been published on choline and the reactions involved in biologic transmethylation by Best and Lucas,[93] Jukes[94] and du Vigneaud.[95]

Jukes[96] has shown that choline is one of the factors required in addition to adequate manganese to prevent slipped tendon in young turkeys. Sure[97] reported that choline is indispensable for lactation in adult rats and in the prevention of paralysis in suckling rats. Depression of the growth rate when choline is omitted from the diet has been observed in the case of the rat by Richardson, Hogan, Long and Itschner,[98] in the chick by Hegsted, Mills, Hart and me[99] and in the dog by Schaefer, McKibbin and me.[100]

The choline requirement, even for the rat, is difficult to establish, since the amount depends on the methionine and betaine content of the ration. Most of the synthetic rations which are now used for experimental work contain 100 mg. of choline in 100 Gm. From this figure one might suggest that the human requirement would be less than 500 mg. a day. It has been estimated that the choline intake from an average human diet may range from 250 to 600 mg. The problem of estimating accurately the choline content of food materials is also a difficult one, since most salts of choline are very soluble in water except a few, like the periodide and the reineckate, which have been used in quantitative estimations. The most specific methods for determining choline are the estimation of acetyl choline after acetylation and the use of the microbiologic assay involving the cholineless mutant (no. 34486) of Neurospora crassa. These methods have been reviewed by Handler.[101]

By far the best dietary source of choline is egg yolk, while soybean meal, liver, dried yeast, pancreas, brain and kidney are good sources. Most edible fats are very low in choline. It should be pointed out that free choline is rarely found in food materials and is present mainly as complex phosphoric acid esters. Most diets contain sufficient choline and its precursors to meet the ordinary needs. However, evidence is accumulating that some types of clinical cirrhosis are favorably affected by dietary treatment including choline and other vitamins, together with a high protein diet.

BIOTIN

Biotin was first recognized as a growth factor for yeast and was isolated by Kögl and Tonnis[102] in 1936. In 1940 du Vigneaud and his co-workers[103] demonstrated that biotin, the yeast growth factor, was the same as the anti-egg white injury factor, or vitamin H, in animal nutrition. György had carried out extensive studies on the properties of vitamin H, and, after it was shown that biotin was identical with this factor, du Vigneaud, Hofmann, Melville and György[104] described the isolation of biotin from liver. The structure was studied by du Vigneaud and co-workers,[105] and its synthesis was announced by Harris and his co-workers[106] in 1943. Free biotin has the structure shown in figure 7. It is a very stable compound, resisting autoclaving with strong mineral acids and in the form found in natural products is but slowly inactivated by alkali. The pure biotin, however, shows appreciable lability to alkali. Both the free and bound biotin are inactivated by oxidizing agents.

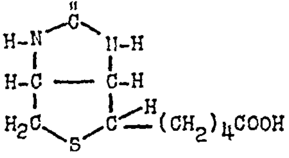

Fig. 7.—Structure of free biotin.

It has been known for many years that a characteristic syndrome can be produced in rats fed diets containing rather high amounts of raw egg white. Lease, Parsons and Kelly[107] observed that the rabbit and the monkey also exhibited a characteristic dermatitis when fed rations rich in egg white. As early as 1933 Parsons, Lease and Kelly[108] concluded that the injury involved an interrelation between a positive toxicity and a relative absence of a protective factor.

György, Rose, Eakin, Snell and Williams[109] have established the presence of "avidin" (an albumin) as the biotin-inactivating factor in egg white. Thus, it becomes apparent that egg white injury is due to the unavailability of biotin by virtue of being tied up with avidin, in which complex biotin cannot be absorbed from the intestine and is excreted in the feces. Nielsen and I,[110] using a more complete ration than had been used in the early work, were able to demonstrate a biotin deficiency in the rat fed 10 per cent levels of egg white. Typical symptoms of "spectacled eye" progressing to general alopecia and, in the later stages, the onset of a spasticity and final death of the animal were recorded. Even the severe symptoms of spasticity were cured when excess biotin (in excess of that which unites with the avidin) was added to the diet. With the synthetic diet without the egg white, these workers were unable to demonstrate any signs of biotin deficiency, and it seems probable that under most conditions the rat can synthesize, through the medium of bacteria in the intestine, sufficient biotin for its requirement. Biotin deficiency has been reported in the chick without resort to egg white diets, which seems to indicate that very limited synthesis of biotin in the intestinal tract must prevail. A typical dermatitis, involving the feet, was observed by Hegsted and his co-workers[111] to be characteristic of the deficiency in the chick, and Patrick and his co-workers[112] also noted similar dermatitis with turkeys on biotin-deficient rations. Waisman, McCall and I[113] described the production

of chronic biotin deficiency in the monkey with biotin-deficient diets and acute biotin deficiency through the use of egg white.

Recent work has established a more definite role for biotin in metabolism. It apparently functions in the carboxylation of pyruvate to yield oxalacetate. Working with Lactobacillus arabinosus, Shive and his co-workers [114] and Lardy and his associates [115] have shown that either oxalacetate or aspartate can partially replace biotin in the growth of this organism. Another function of biotin can be replaced by oleic acid, and Potter and I [116] have shown that when both aspartic acid and oleic acid are present good growth can be obtained in the absence of biotin.

While rather definite requirements can be established for chicks, the requirement for many animals, including man, is difficult to establish, since a large part may be supplied by the intestinal bacteria. Oppel [117] showed that the urinary excretion of biotin in human subjects exceeded that in the diet and in all cases the biotin content of the feces was considerably higher. Sydenstricker and his co-workers [118] reported that dermatitis and changes in the color of the skin which responded to biotin were produced in human subjects by feeding diets with high levels of egg white. Some have experienced difficulty in repeating these observations, but the variations may depend on the degree of intestinal synthesis. In any case, there seems to be no difficulty in supplying an adequate amount of biotin in human beings on average diets.

Biotin can be conveniently determined by use of microbiologic methods of assay in which responses in yeast growth (Snell, Eakin and Williams [119]) or acid production by Lactobacillus casei (Shull, Hutchings and Peterson [120]) are measured. Biotin is rather ubiquitous in distribution, but liver, kidney, yeast and egg yolk are the chief sources. It is to be emphasized that in most tissues biotin is present in a "bound" state, in which it cannot be extracted by hot water, and autolysis or acid hydrolysis must be employed to realize the true concentration of biotin in these instances. Wright [121] summarized methods for the microbiologic determination of biotin as well as the compounds which inhibit the response of microorganisms to biotin.

INOSITOL

Inositol is a crystalline substance with a sweet taste and is a hexahydroxycyclohexane comparable to the cyclic form of glucose. The biologically active form of inositol is one of the optically inactive forms known as i-inositol or meso-inositol, with the stereochemical structure shown in figure 8.

It is a very stable compound, resisting strong acid and alkali treatment. It is found in plants, where it occurs in free form and as "phytin," a calcium magnesium salt of inositol phosphoric acid. In the animal body inositol is found in muscle (accounting for the term "muscle sugar"), brain, blood erythrocytes and eye tissues and as phytin in the red blood cells of chickens and turtles. It also occurs in lipositol, which is a complex containing inositol monophosphate linked to galactose and combined with ethanolamine, tartaric acid, oleic acid and various saturated fatty acids. Aside from its presence in biologic matter in the various forms, little is known about its specific function.

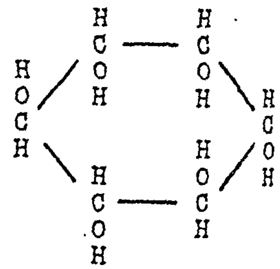

Fig. 8.—Structure of inositol.

The relation of inositol to the nutrition of animals was first indicated by the report of Woolley,[122] who isolated the substance from liver and showed it to be the constituent factor responsible for the cure of mouse alopecia. Later Pavcek and Baum [123] were able to demonstrate a growth response and a cure of spectacled eye in rats. The curative action and growth effect of inositol seems to be related to the amount and type of fat in the diet, since the syndrome was produced on fat-free or low butter fat rations and not on those containing 14 per cent "crisco." A recent report by Lindley and Cunha,[124] who worked with swine, indicates a possible interrelationship between inositol and biotin, and this may explain why inositol was active in the prevention of the spectacled eye condition in rats. Sure [125] has presented data which indicate that inositol may be required by the lactating rat. Martin, Thompson and de Carvajal-Forero [126] have injected rather low levels (10 mg. per kilogram of body weight) of inositol into dogs and observed intestinal motility to be greatly increased. A definite growth increment in the chick was obtained by feeding inositol in conjunction with a synthetic ration.[127] In the rat, inositol was observed to have an effect similar to lipocaic in preventing the fatty livers produced by the feeding of liver fractions or purified biotin preparations.[128]

Inositol can be determined in tissues and foods by using a microbiologic assay employing a specific strain of yeast as the test organism.[129] By this method of determination, Williams and his co-workers [130] have run large numbers of assays on various rat and beef tissues and observed spleen, heart, kidney, brain, thyroid and testes to be especially high in inositol content.

The requirements for inositol are not known. Deficiency symptoms in mice have been cured by feeding 10 mg. of inositol in 100 Gm. of food. Most purified

rations which are now used for experimental purposes contain this level of inositol.

Little is known regarding the role of inositol in human nutrition. Perhaps the most interesting development is the report of Milhorat and Bartels [131] that inositol may improve the action of tocopherol in the treatment of progressive muscle dystrophy. These authors suggested that inositol forms a complex with tocopherol in the intestinal tract and that this complex is necessary for normal creatine metabolism.

PARA-AMINOBENZOIC ACID

Another factor which is often included in the B complex is para-aminobenzoic acid (fig. 9).

It was first recognized as an essential metabolite when Woods [132] discovered the antagonistic action between this compound and sulfanilamide and the consequent identification of para-aminobenzoic acid as a bacterial growth factor.[133] The relation of sulfonamide drugs and para-aminobenzoic acid has been reviewed by Welch.[134] The report by Ansbacher [135] that the graying of the fur observed in rats on certain synthetic rations could be cured by the administration of 3 mg. of para-aminobenzoic acid daily stimulated much interest in this compound as an animal factor. Numerous papers have appeared dealing with this compound as it affects hair color, growth and lactation in rats and other animals, but most of the results are conflicting. Briggs and his co-workers [136] observed a growth response on adding para-aminobenzoic acid to purified rations for chicks, but suggested that it acts indirectly by stimulating the production of unknown vitamins through intestinal synthesis. The possible role of para-aminobenzoic acid in the treatment of gray hair in human beings has been studied by Brandaleone and his associates,[137] who reported that in a group of 19 elderly persons with gray hair only 2 persons showed a significant color change during a period of intensive vitamin therapy. At present there appears to be no clearcut evidence that this metabolite must be supplied preformed in the diet of human beings. The contradictory results which have been obtained may be due to the fact that this compound is a constituent of the folic acid molecule.

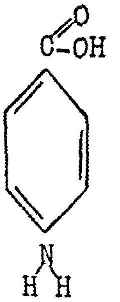

Fig. 9.—Structure of para-aminobenzoic acid.

The most striking observation regarding para-aminobenzoic acid is its chemotherapeutic effect on typhus [138] and Rocky Mountain spotted fever.[139]

FOLIC ACID

Chemically, folic acid is N-[4-{[2-amino-4-hydroxy-6-pteridyl)methyl]amino}benzoyl] glutamic acid, or pteroyl glutamic acid.[140] It is a yellow compound sparingly soluble in water and has the structure shown in figure 10. This molecule contains three different groups: the pteridine part, para-aminobenzoic acid and glutamic acid. The part consisting of the pteridine and para-aminobenzoic acid is called pteroic acid.

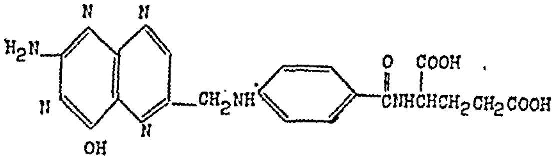

Fig. 10.—Structure of folic acid (pteroyl glutamic acid).

Folic acid is widely distributed in nature, both in free form and in compounds with added glutamic acid, such as pteroyl triglutamic acid (fermentation factor) and pteroyl heptaglutamate (vitamin B_c conjugate).[141]

In light of our present knowledge, it is apparent that folic acid deficiencies were observed over ten years ago in monkeys (Day and his co-workers [142]) and in chicks (Hogan and Parrott [143]). Greatest progress in the isolation of this vitamin was made when it was recognized that a growth factor was needed for the growth of Lactobacillus casei and related organisms [144] and that concentrates of this factor were active for growth and hemoglobin production in chicks fed purified rations.[145]

Most knowledge concerning the function of folic acid has come from studies on bacterial metabolism. Nimmo Smith and Woods [146] have shown that all organisms requiring para-aminobenzoic acid grow equally well when given folic acid, although the required molar concentration of folic acid was greater than that of para-aminobenzoic acid. Folic acid also acted as an antisulfonamide agent with these organisms, although the activity differed from that of para-aminobenzoic acid in that it was noncompetitive. Stokes [147] and Lampen and Jones [148] have suggested that folic acid functions as a prosthetic group in an enzyme concerned with the synthesis of thymine or related compounds.

Today it is well established that synthetic folic acid is required for growth and blood formation in chicks,[149] monkeys[150] and fox and mink.[151] Rats do not require preformed folic acid in the diet until the synthesis of this compound by intestinal bacteria is reduced through the use of sulfonamide drugs.[152] Similarly, dogs grow and regenerate hemoglobin very well on diets devoid of folic acid, although a deficiency can be produced by allowing blacktongue to develop in the dog several times.[153] A folic acid deficiency has been produced in the pig[154] and in the mouse[155] by using an antagonist of folic acid. In most cases the three forms of folic acid show equivalent activity, although there is some evidence that the pteroyl heptaglutamic acid is not as active in the monkey as pteroyl glutamic acid.[150]

The human being is apparently similar to the rat and dog in that the requirement is satisfied by intestinal production except under disturbed conditions. Attempts to deplete volunteer subjects of their tissue reserves of folic acid by supplying diets adequate in other essential nutrients but low in folic acid have not been successful. In spite of this fact, the activity of synthetic folic acid in various types of macrocytic anemia in relapse has repeatedly been demonstrated. The activity of pteroyl glutamic acid was first demonstrated during the latter part of 1945 and the extensive clinical studies have been summarized by Spies and his co-workers,[156] Darby[157] and Cartwright.[158] Darby[157] has also described the effects of pteroyl glutamic acid on the gastrointestinal manifestations of sprue and related syndromes. Since commercial preparations of the classic pernicious anemia factor contain practically no folic acid[159] and since a pure substance, vitamin B_{12}, which is active in very small amounts in the treatment of pernicious anemia, has now been isolated,[160] it is clear that the effect of folic acid may not be direct or that its effect is closely related to additional factors. It is entirely possible that extensive use of vitamin B_{12} in the treatment of anemia in human beings will bring out conditions that will respond only to folic acid. Such a condition has been obtained in the dog on low protein-low niacin diets.[161]

It is difficult to suggest any figures for the folic acid requirement of human beings. Clinical responses have been obtained with 2 to 10 mg., but this intake must be considerably higher than the daily requirement. On the basis of the requirements for other animals, a figure of 0.1 to 0.2 mg. per day may be reasonable.

Microbiologic methods have been used almost exclusively for the estimation of the folic acid content of foods, although chick assays have been used for comparison. In fact, it was the discrepancy between the chick assay and the microbiologic assay which led to the isolation of the conjugate which has activity for the chick but not for bacteria.[162] In 1942 Cheldelin and Williams[163] reported the folic acid content of many foods, but at that time it was necessary to use a standard of assumed potency since the crystalline vitamin was not available. Cheldelin and his co-workers[164] found taka-diastase the most effective of several enzymes studied for the release of folic acid, but later work has shown that a water extract of fresh hog kidney, as described by Bird and his co-workers[165] gives higher results. Olson and his co-workers[166] have studied some of the difficulties encountered in the release of folic acid in liver homogenates. The results of a preliminary report[167] on the folic acid content of foods show liver and deep green leafy vegetables to be very high and green vegetables, cauliflower, kidney, muscle meat and wheat cereals to be high in folic acid values. Preliminary results also indicate that the loss of folic acid during cooking may be very high, although improved methods for the release of conjugated forms may alter the results somewhat. There is also considerable loss in vegetables during storage at room temperature.

COMMENT

So far, ten members of the B complex have been described and a pure compound has been associated with each vitamin. During the early studies on the additional factors required by the chick, Briggs and his co-workers[168] described two factors: one which showed greatest activity in the promotion of growth and one which was more active in stimulating feather production. On the basis of microbiologic assays, which did not include enzymatic treatment for the complete release of folic acid, both appeared to be different from the bacterial growth factor (folic acid), and they were designated B_{10} and B_{11}. When synthetic folic acid became available, an adequate amount added to synthetic rations produced excellent growth, feathering and hemoglobin production. Folic acid appears to replace the two factors, although part of the effect may be indirect. The exact relation of folic acid to vitamin B_{10} and vitamin B_{11} will have to await new technics.

VITAMIN B_{12}

Rickes and his associates [168] have isolated from liver a crystalline compound which is highly active in patients with Addisonian pernicious anemia.[169] On the basis of the aforementioned terminology, this compound has been called vitamin B_{12}. This compound is also active for the growth of Lactobacillus lactis.[170] The availability of this compound for unrestricted experimental work will do much to establish the exact relation of folic acid to macrocytic anemias.

ADDITIONAL FACTORS

The existence of several additional factors is evident from studies with a number of different animal species. In the case of rats, it has been shown that liver and liver preparations will stimulate the rate of growth of these animals when they are maintained on a corn-soybean ration [171] or fed a basal ration with added thyroid.[172] Cary and his co-workers [173] have developed an assay for an unknown factor, called factor X, by prolonged extraction of the casein used in the ration and by depleting the young by feeding their mothers a diet deficient in factor X. Commercial liver extracts were observed to contain this factor. A growth response can be obtained in chicks fed a corn-soybean ration by adding fish products [174] or preparations from cow manure.[175] Chicks maintained on a similar ration also respond to the injection of very small quantities of liver concentrates rich in the pernicious anemia factor.[176] When dogs are placed on diets deficient in niacin and folic acid and containing a sulfonamide drug, the animals finally fail to respond to the addition of these two vitamins. Highly purified liver concentrates given intramuscularly are highly effective in producing growth and hematopoietic responses.[161] Whether the same factor is concerned in all these reactions and whether vitamin B_{12} will function in any of the conditions remains to be determined.

Recent studies show that in monkeys fed highly purified rations deficient in folic acid or riboflavin a type of anemia develops which responds only when fresh liver or raw milk is given.[23] In this case liver concentrates are inactive, which indicates that the factor is separate and distinct from those previously mentioned.[177] This factor may be related to one of the two factors observed to be needed by the fox and mink for normal growth and development.[178]

The availability of the several synthetic water-soluble vitamins has been of the greatest value in clinical practice and also for the fortification of certain foods, but the common foods still remain the best source of these vitamins in practical nutrition. Aside from the gustatory significance of properly prepared natural foods, the greatest value obtained from their consumption is that they supply the unknown factors along with the known. All the known water-soluble vitamins may be obtained from natural foods through proper selection. The selection is not an easy task even with the modern methods of food production and distribution. Some of the modern methods of processing increase rather than decrease the difficulties. Often more emphasis is placed on the mere use of natural foods than on the proper combination of these foods. The few values given in table 1 clearly indicate the fallacy of this emphasis. Different natural foods differ greatly in the amount of any given vitamin which they contain. Thus, apples contain 0.04 mg. and pork loin 1.0 mg. of thiamine in 100 Gm. Eggs supply 0.1 mg. and peanuts 16 mg. of nicotinic acid in 100 Gm. In addition, any one food may show large variations in the amount of the different B vitamins present. Thus, oatmeal contains 0.65 mg. of thiamine, but only 0.14 mg. of riboflavin, in 100 Gm., while liver contains 0.27 mg. of thiamine and 2.8 mg. of riboflavin in 100 Gm.

Table 2.—*Vitamin Content of a Few Commercial Concentrates*

Sample	Thiamine*	Riboflavin*	Niacin*	Vitamin B_6*	Pantothenic Acid*
A	5.0	3.0	20.0	0.5	3.0
B	1.0	1.0	0.15	0.03	0.2
C	2.5	2.5	20.0	0.5	...
D	1.0	0.1	....	...	...
E	1.5	2.0	20.0	0.2	1.0
F	0.6	0.1	....	...	...
G	1.5	2.0	....	...	...
H	1.5	1.0	....	...	...
I	1.0	0.33	5.0	...	...

* Values are given in milligrams per unit of product.

There has been an increasing interest in eliminating the effect of this variation by prescribing vitamin concentrates. In other words, a tablet or a capsule may supply the daily requirement of the vitamins, and any pleasing combination of foods may be consumed for the rest of the day. A survey conducted at the time the first "Handbook of Nutrition" was prepared showed that the concentrates varied to a much greater extent than do natural foods. A resurvey of typical concentrates on the market shows that this variation has decreased to a considerable extent, but one still finds products varying from 0.6 to 5 mg. of thiamine per unit of product. Niacin values vary from 0.15 to 20 mg. These products are useful in the treatment of specific deficiencies, but unless they are properly used they give no greater security than the proper combination of natural foods. Thus, one not only needs to identify all the essential vitamins, but one must give consideration to distribution of these factors in food and food preparations as well as to the daily requirements of human beings.

NUTRITIONAL CONTRIBUTIONS OF WHEAT

The importance of wheat in the basic food economy of most nations of Western civilization has been obvious in recent years. Wheat and wheat flour have frequently played a strategic role in preventing or alleviating mass hunger and starvation in various parts of the world. Wheat flour is one of the least expensive sources of food. Its chief use continues to be for bread. No other single food item is so commonly used to supplement calories supplied by more expensive types of foods.

A 1 pound loaf of plain baker's bread provides about 1,200 calories; a pound of flour provides roughly 1,600 calories. In the proportions in which these food items are included in American dietaries, the slightly lower digestibilities of longer extraction types of flours and of bread made from these are of little practical importance. Half a standard loaf of bread (eight 1 ounce slices), with 1 level teaspoon or one-half an average-sized pat of butter or margarine per slice, provides approximately 900 calories.

Seventy-five to eighty-five per cent of the caloric value of flour is derived from starch. Starch also supplies 60 to 80 per cent of the caloric value of bread, depending on variations in the bread formula. The public, impressed by years of advertising of bread, flour and other grain products as "energy foods" and the association of starch with calories, is unaware that comparable weights or volumes of sugar or fats exceed the caloric values of starch, flour, bread and most other grain products. Our national diet has therefore greatly increased in both sugar and fat (butter excluded) content over the past fifty years, while consumption of flour and bread has declined.

All essential amino acids are represented in the proteins of wheat, flour and bread. The amino acids in these foods do not occur, however, in sufficient or in as well proportioned quantities, relative to human requirements, as in various other food proteins, particularly those of eggs, milk and meats.

The supplementary relationships of bread or flour to various food proteins of animal origin are an important economic factor often overlooked by physicians and nutritionists. Dietary protein derived in proportions of one half to two thirds from foods of plant origin is entirely adequate in quality to meet all protein needs for normal growth, development, reproduction and lactation. As foods of plant origin are usually cheaper than foods of animal origin, the economic benefits of such mixtures are obvious.

The commendable practice of adding 6 per cent dry milk solids to the baker's mix adds a small, but definite, quantity of supplementary animal protein. This practice also adds other important nutrients; namely, calcium and riboflavin. In animal-feeding experiments,[1] the feeding of bread containing 6 per cent nonfat milk solids resulted in improved growth-promoting and bone-calcifying values as well as increased hemoglobin production. Investigators found that "enriched white bread with skim milk solids is the equal of whole-wheat bread in the production of growth and in the production of blood hemoglobin and is distinctly superior to it in the production of bone calcification."

Half a standard loaf of baker's bread provides about 18 Gm. of protein or approximately 30 per cent of the usually recommended need for protein maintenance of normal human adults other than pregnant and lactating women.

The Council on Foods and Nutrition of the American Medical Association as early as 1939 recommended that iron and certain vitamins normally present in wheat but largely removed in the milling of white flour be restored to the flour. This recommendation was made because flour and bread were almost universally consumed by the populace and were especially prominent articles of diet among low income groups whose diets were most in need of improvement in protective food values. Also, many diets might be relatively low in one or more of the essential nutrients now included as enrichment ingredients of white flour and bread. Now approximately 75 to 80 per cent of all white flour and bread is being enriched with thiamine, riboflavin, nicotinic acid and iron according to standards promulgated for enrichment of these products under authority of the Food, Drug and Cosmetic Act. Twenty-three states and two territories to date have enacted laws requiring the enrichment of all family white flour and all baker's white bread. Full scale enrichment would result in an increase of 30 to 40 per cent in the apparent per capita consumption of these three B-vitamins and iron. The enrichment program is of great benefit to the American diet and is of greatest benefit to those whose consumption of bread is highest. These in general are the persons and families with moderate to low incomes.

---

[1] Mitchell, H. H.; Hamilton, T. S., and Shields, J. B.: J. Nutrition 25: 585, 1943.

Apparent per capita consumption of flour in this country declined from about 210 pounds (about 95.2 Kg.) per annum forty years ago to about 155 to 157 pounds (70.3 to 71.2 Kg.) per annum in the years immediately preceding World War II. Consumption increased during the war years, at which time the level was undoubtedly affected by shortages of other foods.

The long and more or less persistent decline in per capita consumption of flour is believed by many to stem principally from three factors: (1) a small decline resulting from decreased expenditure of human energy associated with labor-saving devices and motorized travel, (2) a fairly widespread and gradually rising standard of living associated with the inclusion of higher proportions of certain more expensive foods largely of animal origin in place of breadstuffs and (3) a higher per capita consumption of sugars and sweets and of fats exclusive of butter. Preservation of health demands that the last-mentioned factor be carefully watched, since this trend may increase incidence of obesity and associated diseases. Proper use of foods such as flour and bread which carry important protective food substances must be preserved.

Current Comment

MORBIDITY AND MORTALITY STATISTICS OF DOMESTIC ANIMALS

Reliable morbidity and mortality statistics of domestic animals are unavailable. The veterinarian is required to report certain communicable diseases, but reporting is uncertain and enforcement difficult. The incidence of numerous other diseases is entirely unknown—diseases of great economic importance as well as diseases which may be transmitted to man. The United States Livestock Sanitary Association, the American Veterinary Medical Association and the Division of Biology and Agriculture of the National Research Council have interested themselves in the problem, with the hope that proper legislation may be enacted to correct the situation. The United States Bureau of Animal Industry is cognizant of the need but has neither the funds nor the personnel to initiate the program. The consensus seems to favor compulsory reporting to the office of the state livestock disease control official and thence to the United States Bureau of Animal Industry, with possibly the establishment of a new division of vital statistics.[1] Numerous problems must be solved before the project can be functionally effective. Manuals on nomenclature and on standard methods of diagnosis are in process of preparation but are not yet available. Experiments in the collection of morbidity and mortality data of farm animals have been made in a small way, and should be continued. The shortage of veterinary pathologists will require some years to remedy. The seriousness of the problem, however, from both the economic and the public health point of view, as well as the possible role that infectious diseases of animals might play in biologic warfare, calls for serious attention.

INTERNATIONAL TUBERCULOSIS PREVENTION

Under the sponsorship of the United Nations International Children's Emergency Fund and the Danish, Norwegian and Swedish Red Cross, a program for tuberculosis control on an international basis is being established.[1] The program which is to be carried out in war-ravaged countries of Europe envisages examination of 50,000,000 children and adolescents under 18 years of age. An estimated fifteen million of these children, the report states, will be found to need and will be given BCG vaccine. The bulk of the funds needed ($4,000,000) will be contributed by the United Nations International Emergency Children's Fund, and additional sums are expected from other cooperating organizations. The World Health Organization will provide technical advice and assistance. "Joint enterprise" agreements will be signed between the sponsors and the Ministry of Health of each participating country. Medical teams for actual work will be assembled in each country, composed of nationals and medical personnel supplied by the sponsoring agencies. Fresh vaccine and tuberculin will be supplied by the Danish State Serum Institute until each country is able to supply its own. Tuberculin intradermal or patch tests will be performed on all children, and positive reactors will be vaccinated with BCG. Presumably BCG has protective value for several years. Technical direction of the program is being entrusted to Danish, Norwegian and Swedish personnel because these countries have highly developed the technics of mass vaccination with BCG during the past twenty years ("The tuberculosis death rate in Denmark in 1947 was 30 per 100,000 inhabitants."[1]) Death rates in some of the countries to be included in the program are at least ten times the Danish rates. Joint enterprise agreements have already been signed in Finland, Hungary, Czechoslovakia, Poland and Yugoslavia. In Central Europe alone, as of July 1, 1948, more than 2,000,000 persons have been tested and over 600,000 vaccinated. China, Greece and Italy, as well as other countries of Asia and Western Europe, are being considered for extension of the program. The sponsors of this campaign, realizing that vaccination alone is not sufficient, consider other measures necessary for success to be expansion of public health services for detection of new cases of tuberculosis, furnishing of increased numbers of beds for isolation purposes and training of more adequate numbers of personnel. The program is truly international in that neither national borders nor political, racial nor religious discrimination will interfere with the extension of the program to the war-ravaged areas where greatest need exists.

ORGANIZATION SECTION

Official Notes

COUNCIL ON MEDICAL SERVICE

Southeastern Regional Conference

The Southeastern Regional Conference on Medical Service for 1948 was held at the Columbia Hotel in Columbia, S. C., on October 12 and 13. The Conference met in 1946 and 1947 in Atlanta.

The meeting was opened with an address of welcome by Dr. R. B. Durham, president of the South Carolina Medical Association.

The Tuesday session was devoted to "Rural Medical Service." Mrs. Wilma B. Sledge, social and educational director for the Mississippi State Farm Bureau Federation, discussed "Rural Health Problems and Methods of Their Solution." She gave an interesting résumé of the problems in health of the rural population of Mississippi and of the steps which have been inaugurated and are now in progress toward meeting them. She emphasized the extent to which the shortages of hospital facilities, nurses' and physicians' services are inseparably related to one another and to the shortage of financial resources, in preventing the rendition of totally adequate service.

Dr. William R. Pretlow of Warrenton, Va., discussed the operation of medical and hospital prepayment plans in rural communities. One of the founders of Virginia Medical Service (the medical prepayment plan in Virginia) and now a member of its board of trustees, Dr. Pretlow, who practices in what he described as one of the most completely rural counties of Virginia, showed how the nonprofit prepayment plans, designed to make medical and hospital service more available to the lower income group, could be made to operate on a sound, satisfactory and practical basis in farming areas as well as in the urban centers of population.

Dr. R. V. Platou, head of the department of pediatrics in the Medical School of Tulane University, described the type of survey now being conducted by him and his associates at Tulane, throughout ten counties in southern Mississippi, to determine the extent of the availability of medical care and hospitalization, the existing need and, particularly, the points at which additional medical service and facilities for treatment are essential. Accompanying his remarks with a number of slides showing graphically the findings thus far, Dr. Platou indicated that in the opinion of those engaged in making the survey the matter of supplying the needs would follow more or less automatically once the survey is complete.

The theme of Wednesday morning's program was "Problems of Health in the Southeastern States," and its treatment approached by five speakers from as many different angles.

Dr. C. L. Guyton, head of the division of hospitals of the South Carolina Department of Health, now engaged in administering the program for hospital and health center construction under the terms of the Hill-Burton Act, described in detail what is being done in South Carolina. He pointed out many of the practical difficulties encountered and the minimum requirements that must be met in supplying treatment facilities, if the plan and purpose for which the federal and state funds were appropriated are to be accomplished.

Miss Katherine Edwards, now principal of the elementary schools of Greenville, S. C., spoke of the practical side of health problems among school children. From her own experience, Miss Edwards made it clear that a teacher alert to the reaction of her pupils can generally tell when all is not right with their health, and that the teacher should be encouraged to concentrate on detecting illness and lending her aid in the improvement of the child in this respect as well as in mental training. The chief emphasis of her discussion was on the fact that problems of this sort will have to be solved primarily by two groups, the teachers and the physicians. Both of these professional groups with background, point of view and occupation so directly related to the physical and social well-being of the people must recognize, she pointed out, and concentrate on discharging the responsibilities for which their training and professional status have fitted them.

Mr. W. Cicero Kendrick of Atlanta, a prominent leader in organized labor and an official of the Georgia State Federation of Labor, pointed out that labor as a group is just as vitally interested as any other in preserving the freedom and independence of the American way of life, and that employees recognize that their welfare depends on the welfare of the employer. This mental attitude, however, and that of other groups, do not alter the fact that many persons, he said, are without adequate medical care and hospital service, through circumstances beyond their immediate control. While he did not favor a system of state medicine such as has often been discussed, he expressed the belief that this might be the ultimate result unless some other solution is found. He called on the medical profession to furnish the leadership in finding such a solution and pledged the cooperation of labor and other lay groups in any movement reasonably calculated to relieve the situation.

Dr. John T. T. Hundley of Lynchburg, Va., presented the results of a survey conducted by him a few months ago, in determining what the lay public generally thinks of the adequacy of available medical care and the things which need most to be changed to improve it. Dr. Hundley, who is a practicing physician specializing in internal medicine, sent requests to a large number of people in various occupations and strata of society, requesting their estimate of doctors and the service rendered by them. Some of the replies he received were enlightening and highly interesting, if not always entirely complimentary. The attitude consistently expressed by the majority of those who replied was favorably inclined toward the medical profession.

Comments on the subject from the standpoint of a Washington observer were given by Dr. Joseph S. Lawrence, of the Washington office of the American Medical Association Council on Medical Service. Dr. Lawrence brought valuable observations regarding the probable future trends. He called attention to the numerous bills introduced in the last Congress, some of which were passed, affecting one phase or another of the subject of medical care for all people.

Dr. Walter B. Martin of Norfolk, Va., a member of the Board of Trustees of the American Medical Association, outlined the steps taken by the national organization within the past few years in its active program to preserve the free system of the practice of medicine. He stressed the Ten Point Program of the American Medical Association, adopted and now in process of execution. This, he believed, if properly activated and extended, should go far toward answering criticism leveled at the profession in the past, and remedy most of whatever defects exist in the system of medical service which has always been a part of democratic free American institutions.

After luncheon at 1 p. m., with members of the Conference guests of the South Carolina Medical Association, the discussion was resumed, the afternoon being devoted to general discussion, led by Mr. Thomas A. Hendricks of Chicago, Executive Secretary of the American Medical Association Council on Medical Service, and Dr. Fred C. Hubbard of North Carolina.

The two day meeting was attended by representatives of the medical associations of North Carolina, Virginia, Georgia, Florida, Tennessee, Louisiana and South Carolina. The total number registered was 53, and the general consensus seemed to be that the program arranged was successful in focusing the thought and presenting prepared discussions on those subjects of most vital interest to the profession, in its quest for an answer to the questions which have been so prominent in the minds of the public for one reason or another during the past few years. No formal action was determined upon and none was proposed by the Conference. The ideas expressed were for the further consideration of the delegates in their respective state groups and for approval wherever possible, according to the means most adaptable in each area.

The arrangements for the Conference were in charge of a committee composed of Dr. Julian P. Price, chairman; Dr. Walter B. Martin and Dr. H. B. Mulholland, dean of the University of Virginia Medical School, Charlottesville, and a member of the American Medical Association Council on Medical Service. Dr. Mulholland presided at the first day's session and Dr. Price presided on Wednesday. Mr. M. L. Meadors, director of public relations and counsel of the South Carolina Medical Association, and Henry S. Johnson, director of public relations and medical service of the Medical Society of Virginia, took part in the meeting.

Washington Letter

(From a Special Correspondent)

Nov. 22, 1948.

Report of Office of Civil Defense Planning

Medical and public health responsibilities of a home defense program for the United States are sharply defined in the blueprint for organization which has been submitted to Secretary of Defense James Forrestal by the Office of Civil Defense Planning. Its report recommends establishment by Congress of a permanent Office of Civil Defense and subsequent enactment by states and municipalities of supporting laws which would be required to integrate the system.

The director of the proposed Office of Civil Defense would report to the Secretary of Defense or directly to the President. In his 300 page printed report to Secretary Forrestal, Chairman Russell J. Hopley of the Office of Civil Defense Planning said the former is preferable. Four deputy directors are provided for: Plans and Operations, Medical and Health Services and Special Weapons Defense, Technical Services, Training. The medical deputy "should be an outstanding member of the medical profession, licensed to practice medicine and surgery, and have had broad medical and administrative experience."

Under his general supervision wuold be four broad divisions: medical and health services, radiologic defense, chemical defense and "other special weapons defense," the last-named division concerning itself with a subject which is still alluded to only inferentially in government documents — biologic warfare. Bureaus organized similarly would be set up by the several states, cities and metropolitan areas.

"In modern total warfare," says the Hopley report, "the civilian frequently is subjected to enemy attack to an extent comparable to that experienced by the soldier. An attacked civilian population demands the same treatment of casualties and the sick, and protection against communicable diseases that is required by the military forces. In crowded urban areas, deaths, disability and suffering resulting from enemy action can easily exceed any which has ever been experienced by armies. In such instances, unless there is adequate provision for the preservation of the health and lives of the civilian population, the consequent reduction in civilian manpower, working effectiveness and morale will so cripple our industries as to make defeat more than a possibility. There can be no satisfactory civil defense without adequate provision for medical and health defense."

Headed by a physician, the medical and health services division would have three branches: medical care, public health and administration. In peacetime, the branch chiefs might serve on a part time basis, except that administration would be a full time activity, staffed by the Army, during peace as well as war. The public health and medical care services branches are subdivided into specialty sections, the heads of which would serve as consultants in peacetime.

The chief of the radiologic defense division would hold a doctorate degree, preferably in medicine, and should be a career man in government service, says the report. This division would have a five member advisory committee. A medical and health advisory committee also is recommended, its members representing the following organizations: Red Cross, National Research Council, American Medical Association, American Dental Association, American Association of Industrial Physicians and Surgeons, American Public Health Association, Association of State and Territorial Health Officers, American Veterinary Medical Association, American Nurses Association, American Hospital Association, Catholic Hospital Association, American Protestant Hospital Association and the American Pharmaceutical Association.

In making the Hopley report public, Secretary Forrestal explained that he wished to stimulate general discussion of the issue even before details of the plan are approved by his and other government agencies. Mr. Hopley, in a letter accompanying transmittal of the report to state governors, said in part:

"While my own planning group is naturally convinced of the soundness of its recommendations, it is obvious that a report which concerns the entire civilian population and is of interest to so many governmental agencies must be subjected to the most careful scrutiny and review before it can finally be approved. . . . When all these comments have been received and considered, the report in its present form, or as modified as a result of such consideration, will be referred to the President for approval and subsequent submission to the Congress."

Dr. Perrin H. Long, professor of preventive medicine at Johns Hopkins University School of Medicine, served as medical advisor to the Office of Civil Defense Planning. Its consultant in radiologic defense was Dr. George M. Lyon, of Veterans Administration. Each was assisted by an advisory committee.

The report, whose 300 pages of text are supplemented by 17 organizational charts and proposed model legislation on federal, state and local levels, is purchasable ($1) from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C.

"Keto-Bemidone" Held Too Dangerous for Clinical Use

After investigation of the drug at the U. S. Public Health Service special hospital at Lexington, Ky., the Committee on Drug Addiction and Narcotics, National Research Council, has advised the Bureau of Narcotics and Food and Drug Administration that K-4710, "keto-bemidone" (4-[metahydroxypheny]-1-methyl-4-propionyl piperdine hydrochloride) has addictive properties too great to justify its distribution as an analgesic. The drug was submitted for assay last January by Winthrop-Stearns, Inc.

Coming Medical Meetings

American Medical Association Interim Session, St. Louis, Municipal Auditorium, Nov. 30-Dec. 3. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Conference of State Secretaries and Editors, St. Louis, Hotel Statler, Nov. 28-29. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

National Medical Public Relations Conference, St. Louis, Hotel Statler, Nov. 27. Mr. Lawrence W. Rember, 535 N. Dearborn St., Chicago 10, Director.

American Academy of Allergy, Atlantic City, Chalfonte-Haddon Hall, Dec. 6-8. Dr. Theodore L. Squier, 425 E. Wisconsin Ave., Milwaukee 2, Secretary.

American Academy of Dermatology and Syphilology, Chicago, Palmer House, Dec. 5-9. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, Secretary.

American Society of Tropical Medicine, New Orleans, Roosevelt Hotel, Dec. 5-9. Dr. Frederick J. Brady, National Institute of Health, Bethesda 14, Maryland, Secretary.

Association for Research in Nervous and Mental Diseases, New York, Waldorf-Astoria Hotel, Dec. 10-11. Dr. Clarence C. Hare, 700 W. 168th St., New York 32, Secretary.

Eastern Section, American Federation for Clinical Research, Philadelphia, Temple University School of Medicine, Dec. 4 Dr. J. Edward Berk, Temple University School of Medicine, Philadelphia, Chairman.

Puerto Rico, Medical Association of, Santurce, Dec. 10-12. Dr. J. Basora Defillo, Box 3866, Santurce, Secretary.

Radiological Society of North America, San Francisco, Dec. 5-10. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Southern Psychiatric Association, Dallas, Texas, Hotel Adolphus, Dec. 6-7. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southern Surgical Association, White Sulphur Springs, W. Va., Dec. 7-9. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Western Surgical Association, St. Louis, Dec. 2-4. Dr. Warren H. Cole, 1853 W. Polk St., Chicago 12, Secretary.

GOVERNMENT SERVICES

SELECTIVE SERVICE SYSTEM

EDUCATIONAL ADVISORY COMMITTEE

The Director of Selective Service, Washington, D. C., issued on November 2 a memorandum to all local boards outlining the recommendations of the National Headquarters with respect to the deferment of preprofessional and professional students. This memorandum announced that the Director had established a Healing Arts Educational Advisory Committee, the purpose of which is to recommend means by which sufficient personnel may be trained in the healing arts, through the maintenance of an adequate flow of students through professional and preprofessional schools; to recommend procedures by which an adequate flow of students through the professional schools might be maintained to meet the nation's needs in trained medical, dental, veterinary and osteopathic personnel, and to advise the educators on problems arising through the operation of the Selective Service Act of 1948.

The Committee consists of Donald G. Anderson, M.D., representing the Council on Medical Education and Hospitals of the American Medical Association, Stockton Kimball, M.D., representing the Association of American Medical Colleges, G. D. Timmons, D.D.S., representing the Association of American Dental Schools, Dr. B. T. Simms, D.V.S., representing the American Veterinary Medical Association, and Otterbein Dressler, D.O., representing the American Osteopathic Association.

Students in Professional Schools: The Committee has advised the Director of Selective Service that the national interest will require graduates of medicine, dentistry, veterinary medicine and osteopathy annually in numbers equal at least to the present level. It recommends that students properly enrolled in the professional schools of these four professions and satisfactorily pursuing full time courses leading to graduation should be permitted to continue their studies until graduation.

Students in Preprofessional Schools: The Committee also recommends that sufficient numbers of preprofessional students be made available to maintain the freshman classes of these professional schools at present levels. To accomplish this the Committee recommends that these professional schools select provisionally for admission, on completion of the preprofessional course to the satisfaction of the professional school, certain students who have satisfactorily completed at least one year of the preprofessional course. These provisional admissions will continue valid until the following July 15 unless cancelled by the professional school.

The number of preprofessional students who are not otherwise deferable and who have completed at least one year of professional work and who may be selected, is, for the freshman class of 1949, 55 per cent of the 1948 freshman professional class; for the freshman class of 1950, 62½ per cent of the 1948 freshman professional class, and for the freshman class of 1951, 100 per cent of the 1948 freshman professional class.

These percentages of provisional admissions are to be reviewed by the Committee once each year, and recommendations as to the numbers will be adjusted for the ensuing classes in accordance with the demonstrated needs at that time.

Identification of Professional Students and Preprofessional Students Provisionally Accepted: To identify to local Selective Service Boards the professional students of medicine, dentistry, veterinary medicine and osteopathy, and the preprofessional students who have been provisionally admitted to the professional schools, the Committee has recommended that an authorized representative of the professional schools should submit, on a form designed for that purpose, (1) the names of professional students who are not otherwise deferrable under the Selective Service Act of 1948 and who have duly matriculated in their professional schools and are actually pursuing a course leading to graduation in one of the specified professions and (2) the names of preprofessional students who have completed at least one year of preprofessional study and have been provisionally accepted for entrance into the professional school on completion of a preprofessional course to the satisfaction of the professional school.

Certification of Preprofessional and Professional Students: The form to be used by the professional schools will be Certification of Preprofessional and Professional Students of Medicine, Dentistry, Veterinary Medicine and Osteopathy (SSS form no. 103). Such certificates will be issued to local boards through national headquarters and state headquarters for Selective Service, and will constitute evidence in support of the student's claim for occupational classification. Before issuing a certificate for a preprofessional student, the professional school should secure assurance from the student that he will not obtain a similar certificate from another professional school.

Failure to Pursue Course of Study Satisfactorily: When a student fails to pursue his course satisfactorily to the professional school, an authorized representative of the school will cancel the Certification of Preprofessional and Professional Students of Medicine, Dentistry, Veterinary Medicine and Osteopathy (SSS form no. 103) and will notify the local board of such cancellation, through national headquarters and state headquarters of Selective Service.

NAVY

COUNCIL ON RADIO-BIOLOGICAL RESEARCH

The Council on Radio-Biological Research of the Bureau of Medicine and Surgery recently held its first meeting at the Naval Medical Research Institute, Bethesda, Md. Captain R. H. Draeger, M.C., U.S.N., head of the Research Branch, Atomic Defense Division, Bureau of Medicine and Surgery, acted as chairman. Representatives from the Office of the Surgeon General of the Army, the Armed Forces Special Weapons Project, U. S. Atomic Energy Commission, Naval Radiologic Defense Laboratory, Office of Naval Research and Naval Medical Research Institute were present. The function of this council is to review all proposed research projects in the fields of radiation biology, diagnosis and therapy of radiation illness, internal radiation hazards and methods of photographic dosimetry and personnel decontamination; to assign equitable priority to such projects, and to recommend such projects to the proper laboratory for investigation.

TRAINING IN CIVILIAN INSTITUTIONS

The following lieutenants (jg) of the Medical Corps Reserve have been ordered to active duty at civilian medical institutions as interns under the Medical Training Program: William C. Adams Jr., of Boise, Idaho, to St. Johns Hospital, Santa Monica, Calif.; Frederick Brockmeier of Glendale, Ohio, to Christ Hospital, Cincinnati; William B. Buckingham of Oak Park, Ill., to Cook County Hospital, Chicago; John L. Falls of River Forest, Ill., to Cook County Hospital, Chicago; Richard R. Grayson of Maywood, Ill., to Cook County Hospital, Chicago; Rice T. King of Jacksonville, Fla., to Baltimore City Hospitals, Baltimore; William H. Kittrell of Mt. Pleasant, Tenn., to Philadelphia General Hospital, Philadelphia; Martin H. Klein of Fountain City, Wis., to City Hospital of Akron, Akron, Ohio; Robert S. Meador of Leonard, Texas, to Scott and White Hospital, Temple, Texas; Hale B. Soyster Jr., of Los Angeles, to Los Angeles County General Hospital; Harold E. K. Sweeny of Elizabeth, N. J., to Wesley Memorial Hospital, Chicago;

Edward E. Tennant of Cleveland to Christ Hospital, Cincinnati; John F. Westfall of Glendale, Ariz., to Gallinger Municipal Hospital, Washington, D. C.; Jack S. Woodruff of Columbus, Ohio, to Indianapolis City Hospital, Indianapolis, and Belton J. Workman Jr., of Woodruff, S. C., to Roper Hospital, Charleston, S. C.

NAVAL OFFICERS AWARDED MEDAL AND PRIZE

The Association of Military Surgeons of the United States recently announced that two officers of the Naval Medical Research Institute, Bethesda, Md., had been awarded the Sir Henry Wellcome Medal and Prize. The recipients are Lieut. Comdr. Eugene P. Cronkite, M.C., U.S.N., and Lieut. (jg) William H. Chapman, M.S.C., U.S.N. Their paper, "A Critical Analysis of the Syndrome of Acute Total Body Radiation Illness," was selected by the association as the best submitted in the annual competition. The honorarium and scroll accompanying the award were presented by Brig. Gen. Edgar Erskine Hume, U.S.A., president of the association, November 12 at the annual convention in San Antonio, Texas. Dr. Cronkite is head of the Hematology Facility, Naval Medical Research Institute, and Lieutenant Chapman is a member of the staff.

CLINICAL PSYCHOLOGISTS WANTED FOR REGULAR CORPS

Applications are desired from Naval Reserve officers who hold the Ph.D. in psychology, or have completed all course work for this degree, for transfer to the regular navy, medical service corps (clinical psychology). Officers who are accepted for appointment will be assigned to clinical psychology billets, neuropsychiatry service in continental Naval hospitals, Naval and Marine training centers, retraining commands, and disciplinary barracks. Previous military experience in psychology is not a requisite; however, preference will be given to reserve officers who filled psychologic billets during World War II. Applications should be initiated through the Naval districts in which the applicant resides; however, more detailed information can be secured from the Navy Department, Bureau of Medicine and Surgery, Attention: Professional Division, Washington, D. C.

RETIRED OFFICERS REQUEST ACTIVE DUTY

The following retired medical officers have requested recall to active duty: Capt. Harold A. Noreen, Minneapolis, to 9th Naval District as assistant to the district medical officer in connection with the Medical Reserve Program; Comdr. Norman J. Haverly, Long Beach, Calif., to the Office of Naval Office Procurement, Los Angeles, and Comdr. Esdras J. Lanois, Cleveland, to the Administrative Command, Naval Training Center, San Diego, Calif., for duty in the Medical Department.

NEW NAVY INTERNS

The Bureau of Medicine and Surgery announced October 27 that thirty-two additional lieutenants (jg) in the Medical Corps Reserve have reported for their first active duty in internships at various civilian medical institutions under the Navy Medical Training Program. These officers will serve on active duty in the Navy after completion of their internships.

AWARDS AND COMMENDATIONS

Lieutenant Arlington Bensel Jr.

Lieutenant Arlington Bensel Jr., U.S.N.R., of East Orange, N. J., has been authorized by the Navy Department to wear the Presidential Unit Citation ribbon with star by virtue of his service with the First Marine Division, which was cited by the President of the United States "for extraordinary heroism in action against enemy Japanese forces at Peleliu and Ngesebus from Sept. 15 to 29, 1944."

PERSONALS

Lieutenant (jg) Frank R. Johnson of LaGrange, Ill., has accepted appointment in the Regular Navy Medical Corps and has been nominated for duty under instruction in a residency in surgery at the Presbyterian Hospital, Chicago.

Lieut. (jg) Harry C. Alfred of St. Joseph, Mo., will report for his first active duty in the Medical Corps Reserve at the Naval Hospital, Memphis, Tenn.

Lieutenant (jg) Nathaniel M. Cohen Jr., Brookline, Mass., has transferred from the active reserve to the regular navy.

VETERANS ADMINISTRATION

DOCTORS NEEDED IN TUBERCULOSIS HOSPITALS

One hundred full time doctors are needed by Veterans Administration for duty in its tuberculosis hospitals. Applicants should address their inquiries to the Chief Medical Director, Veterans Administration, Washington 25, D. C. The openings are scattered throughout the nation among Veterans Administration hospitals specializing in the treatment of tuberculous veterans and in Veterans Administration general hospitals operating tuberculosis departments.

The salary scale for full time doctors in the Veterans Administration's Department of Medicine and Surgery ranges between $4,479 and $10,305 annually for jobs now open. During the past year, 18,222 tuberculous veterans were admitted to Veterans Administration hospitals for treatment. Discharges during the same period totaled 18,071.

SITE FOR NEW HOSPITAL AT CLEVELAND

The Administrator of Veterans Affairs, Carl R. Gray Jr., has authorized the acquisition of twenty acres of land at Cleveland for a 1,000 bed veterans general hospital. The tract, which is less than a mile from the Western Reserve University Medical School, now has on it fifteen mansion type dwellings, some of which will be used as auxiliary hospital buildings. The City Council, it is said, will vacate the portion of Magnolia Drive lying within the perimeter of this tract and relocate all utilities lying in the bed of the street.

PERSONALS

Dr. Edward S. Post has become manager of the Veterans Hospital at Battle Creek, Mich., succeeding Dr. Roger P. Hentz.

Dr. William S. Schwartz of Portsmouth, Ohio, has become chief of professional services at the Veterans Administration hospital units at Oteen and Swannanoa, N. C. Dr. Schwartz formerly was chief of tuberculosis services at the veterans hospital at Brecksville, Ohio.

Dr. Arthur J. Klippen, chief medical officer at the Saginaw, Mich., subregional district office of the Veterans Administration, has been appointed chief of professional service with offices in Detroit. Dr. Klippen resigned as secretary of the Saginaw County Medical Society on acceptance of his new post and will move to Detroit. He was a lieutenant colonel in the Army Medical Corps during the recent war.

E. Burns Geiger, formerly of Hagerstown, Md., has been appointed chief of the Pharmacy Division of the Veterans Administration Department of Medicine and Surgery. Mr. Geiger served in the Navy during the war and later became assistant to the chief of the Division of Pharmacy.

HOSPITAL NEWS

The Veterans Administrations announces that the contract for the construction of a 131 bed addition to the Veterans Administration hospital at Brecksville, Ohio, has been awarded for $937,000.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARKANSAS

Dr. Roberts Resigns as Dean.—Dr. Joseph T. Roberts, University of Arkansas School of Medicine, Little Rock, has resigned as dean and head of the department of medicine. Dr. William C. Langston, assistant dean and professor of anatomy, has been named acting dean. Dr. Langston, a graduate of the State University of Iowa College of Medicine, Iowa City, 1929, has been on the faculty of the school since 1930.

Narcotic Violation.—According to the Bureau of Narcotics, Dr. James H. Cole, Morrilton, pleaded guilty in the U. S. District Court at Little Rock August 30 to a charge of violating the federal narcotic code, and on that date was sentenced to serve a term of five years and thereafter will be placed on probation for a like period, with the provision that he should not practice medicine in any form.

CALIFORNIA

Society News.—Dr. Paul H. Pernworth, Compton, addressed the Southeastern Branch of the Los Angeles County Medical Association, November 3, on "Therapeutic Applications of Regional Anesthesia." The Los Angeles Obstetrical and Gynecological Society elected Drs. L. Grant Baldwin, president, and Gordon Rosenblum, secretary-treasurer, for the coming year.

Dr. Starr Appointed Acting Chairman of Department.—Dr. M. Paul Starr, clinical professor of medicine of the graduate division of the University of Southern California School of Medicine, Los Angeles, has been appointed professor and acting chairman of the department of medicine. Dr. Starr came to the university in 1945 after serving in the Army Medical Corps. He is a graduate of Rush Medical College, 1922, and beginning in 1924 he served on the staff of Northwestern University School of Medicine.

COLORADO

Courses for General Practitioners.—A course for general practitioners in Colorado and neighboring states will be conducted at the University of Colorado Medical Center, Denver, between December 13 and 17, through the joint sponsorship of the Colorado State Medical Society and the University of Colorado School of Medicine. This course is planned to give general practitioners instruction in recent developments in the diagnosis and treatment of diseases involving the cardiovascular and gastrointestinal systems, as well as disorders connected with endocrines, metabolism, the hemopoietic system and the chest. Fifty per cent of the time will be given to free discussion and presentation of questions by the participants. The course is open to licensed physicians in the Rocky Mountain region in general who are members of their respective state medical societies. A registration fee is required of all applicants. The tuition is $20. Interns and residents are invited to register and take part in the course without charge. Director of the course is Dr. Robert S. Liggett, professor of medicine.

A course in anesthesiology for general practitioners will be given at the Medical Center, January 12-15, 1949, sponsored by the Colorado State Medical Society, the Colorado State Society of Anesthesiologists, the University of Colorado School of Medicine and the Denver Society of Anesthesiologists. Except for interns, eligibility and fees are the same as for the course in general medicine. The director of the course is Dr. Philip A. Lief, associate professor of anesthesiology. For information, write the Director of Graduate and Postgraduate Medical Education, University of Colorado Medical Center, Denver.

CONNECTICUT

Professor Watkins Dies.—Professor John H. Watkins, Ph.D., associate professor of public health at Yale University and associated with the university since 1928, died in New Haven September 25, aged 47.

Personals.—Dr. Adrian C. Moulyn of the Yale Plan Clinic at New Haven has been appointed staff psychiatrist of the new clinic for the care and treatment of alcoholic addicts at Stamford, Conn. Dr. Moulyn is a graduate of the medical school of the University of Utrecht, Holland, in 1930. He has been an instructor in psychiatry and mental hygiene at Yale University School of Medicine.——Dr. Francis L. Lundborg, West Hartford, was appointed medical director at Trinity College succeeding Dr. Horace C. Swan, Hartford, who retired in June. Dr. Lundborg, a graduate of Yale Medical School, New Haven, 1930, formerly assisted Dr. Swan in the health program for Trinity students.

Yale Library Opens to State Physicians.—Medical reference material formerly limited to Yale medical students and faculty has been made available to Connecticut physicians through the recent creation of the Associates of the Yale Medical Library. More than one hundred and sixty physicians have become associates since the group's inception two months ago. Invitations to membership are being sent to Connecticut doctors and Yale medical alumni throughout the nation. The associates are granted borrowing privileges of the library and will receive its bulletins including accession lists and notices of important meetings. To expand further the facilities and services of the library the associates will pay a small annual subscription fee and are urged to contribute books and other material that will enhance the library. Officers of the associates are Dr. Herbert Thoms, chairman, Dr. Levin L. Waters, secretary, Laurence G. Tighe, treasurer, all of New Haven, and Dr. George Blumer, San Marino, Calif., former dean of the school of medicine, honorary chairman.

Silver Hill Foundation Medical Council Meeting.—At the annual meeting of the Silver Hill Foundation Medical Council in New Canaan in October, the subject for discussion was "What is the Ideal Method of Treating the Psychoneuroses, Psychosomatic Illnesses and Psychosocial Disorders?" Speakers were Drs. Harold L. Amoss, Greenwich; Arlie V. Bock, Boston; Walter O. Klingman, Charlottesville, N. C.; Fredrick C. Redlich, New Haven, and Edwin G. Zabriskie, New York. The Silver Hill Foundation is a psychotherapeutic unit devoted to the study, care and treatment of the psychoneuroses where patients are given brief, intensive psychotherapeutic and physiologic aid. The medical staff is composed of internists who, although they are specialists certified by the American Board of Psychiatry and Neurology, are interested in the eclectic approach to the treatment of the psychoneuroses rather than adhering to any one formal school of psychiatry. The medical director of the foundation is Dr. William B. Terhune of New Canaan and New York. Members of the council are outstanding physicians from various sections of the country.

DISTRICT OF COLUMBIA

Borden Lectures Revived.—Dr. John McMichael, professor of medicine at the University of London, delivered the William C. Borden Lecture November 15 at George Washington University School of Medicine. Dr. McMichael's address, "Some Peripheral Vascular Reactions of Surgical Interest," revived the Borden lectures, which were discontinued during the war. The lectures are made possible by a fund established by the Borden family in memory of the late Dr. William C. Borden, formerly dean of the medical school. Dr. McMichael has recently returned from a lecture tour of the United States and Canada. In addition to being professor of medicine at the University of London, Dr. McMichael is professor of medicine at the British Post-Graduate Medical School and chief of medicine at the Hammersmith Hospital in London.

ILLINOIS

Lecture on Atomic Injuries.—The Peoria County Medical Society in conjunction with the 203d Medical Battalion, Illinois National Guard, will have a dinner and lecture December 7 in the Pere Marquette Hotel, Peoria, at 8 p. m. Lieut. Col. John R. Hall Jr., U. S. Army Medical Corps, and former X Corps Surgeon in Japan, will speak on "Treatment of Atomic Bomb Injuries." All physicians and medical officers of the guard are invited.

Tuberculosis Mortality at Record Low.—The Illinois State Department of Public Health reports that mortality from tuberculosis in the state in 1947 was lower than in any previous year of record. The death rate of 33.6 per 100,000 population was about 9 per cent below that for 1946. During the past two decades mortality reports show that tuberculosis has declined by more than 50 per cent. In 1927 the rate was 74.9, and in 1937 it had dropped to 44.2 per 100,000 population. The State Department of Public Health has placed in operation seven mobile x-ray units, through which service more than 250,000 persons received roentgen examinations of their chests in 1947. Many additional units are also being operated in the state by local official and voluntary health agencies. To provide additional facilities for the care of tuberculosis patients, the state has developed plans and appropriated funds for the construction of two new sanatoriums: one of 100 bed capacity to be located at Mt. Vernon and another of 500 bed capacity to be located in Chicago.

Chicago

Dr. Cannon Receives Awards.—Dr. Paul R. Cannon, professor and head of the department of pathology at the University of Chicago, recently received two awards, the William Wood Gerhard Gold Medal of the Pathological Society of Philadelphia for outstanding work in medical research and the Ward Burdick Award-Medal of the American Society of Clinical Pathologists for outstanding contributions to pathology. Dr. Cannon received his medical degree in 1925 from the Rush Medical College.

Society News.—At the meeting of the North Side Branch of the Chicago Medical Society at the Drake Hotel December 2, Dr. Mayo H. Soley, dean and research professor in clinical medicine, State University of Iowa College of Medicine, Iowa City, will speak on "Present Status of Radioactive Iodine in Treatment of Toxic Goiter." The second address will be given by Dr. Paul S. Rhoads of Northwestern University Medical School, on "Inhalation of Penicillin Dust: Its Role in Respiratory Diseases."

Tons of Dust Per Square Mile.—During September Chicago air contained less dust than during any other month since the city began recording dust fall in 1926, according to the city's smoke inspector. The average dust fall was 34.65 tons per square mile, compared with the previous low of 36.5 tons in December 1940. The average was 51.53 tons in September 1947 and 41.1 tons in August 1948. The average soot fall in September was 9.26 tons, compared with 7.56 in August. The decline in dust fall is attributed in part to the campaign to curtail railroad and factory smoke.

Drs. Ivy and Youmans Cited for Wartime Service.—Dr. Andrew C. Ivy, vice president of the University of Illinois, received the president's certificate of merit, and Dr. John B. Youmans, dean of the college of medicine, the Army and Navy certificate of merit, November 6. The certificates are given in recognition for the wartime services of distinguished scientists and engineers of the Office of Scientific Research and Development. Major General John F. Lucas, deputy commander of the Fifth Army, and Captain Phillip G. Stokes, commandant of the Naval R.O.T.C. at the University of Illinois, presented the certificates.

Research Grants to Illinois.—The University of Illinois College of Medicine has been awarded the following grants for research: Office of the Surgeon General, Department of the Army, has awarded a $10,000 grant for the "Pharmacodynamic Study of Renal Blood Flow," to be conducted by the department of pharmacology, under the supervision of Dr. Jules H. Last. The U. S. Public Health Service has awarded the college of medicine separate grants of $6,000 and $5,500 for visual education depicting clinical manifestations of uterine carcinoma to be undertaken under the supervision of Dr. Frederick H. Falls in the department of obstetrics and gynecology, and for a study of the physiologic effects of the influenza virus on the mammalian host to be conducted under the supervision of Dr. John E. Kempf in the department of bacteriology. A $5,000 grant has been received from Parke, Davis and Company for the development and evaluation of antihistamine and adrenergic blocking agents under the supervision of Earl R. Loew, Ph.D., in the department of pharmacology. A research project on "urogastrone" will be conducted by the department of clinical science through a grant of $3,960 from Ayerst, McKinnon and Harrison, Ltd., under the supervision of Dr. Morton I. Grossman.

KENTUCKY

Hospital News.—Work on the Our Lady of Peace Hospital in Louisville, which is expected to cost more than $2,000,000, was begun in September. It is the first of fifteen projects approved for Kentucky under the federal hospital survey and construction program. The hospital will be operated by the Sisters of Charity of Nazareth.

LOUISIANA

Establish Musser Lectureship.—The Tulane University of Louisiana School of Medicine, New Orleans, will annually sponsor a series of lectures at the university in honor of the late Dr. John H. Musser, who served for more than twenty years as professor of medicine. The first lecture was held November 12, when Dr. John McMichael of the Postgraduate Medical School of London, England, spoke on "The Principle of Venous Pressure Reduction in the Treatment of Congestive Heart Failure." The university plans to hold lectures twice a year, bringing to New Orleans international figures in medical science.

MICHIGAN

Study of Venereal Disease Control.—A new research study in case finding in venereal disease control is being conducted under the joint sponsorship of the Michigan Department of Health and the U. S. Public Health Service, with the cooperation of the local health departments of the state. The object is to find out what is wrong with the current methods of case finding. The study is set up so that within twenty-four hours after a patient with venereal disease has been interviewed at the Michigan Rapid Treatment Center at Ann Arbor or the Social Hygiene Clinic, Detroit, investigations of the contacts can begin. Research began November 1 and will continue until June 30, 1949.

MISSOURI

Personal.—Dr. Edward H. Dunn, St. Louis, now a resident physician at the Veterans Administration Hospital, Jefferson Barracks, has been appointed for missionary service in Fort Yukon, Alaska, where he will be in charge of the Hudson Stuck Memorial Hospital. Dr. Dunn is a graduate of the Washington University School of Medicine, St. Louis, 1943, and served in the Medical Corps from 1944 to 1946.

Public Health Scholarship Fund.—A drive for funds to establish a public health scholarship in honor of Dr. Joseph F. Bredeck is being organized by friends and associates of the late St. Louis health commissioner. Dr. Joseph C. Peden, Missouri Theater Building, St. Louis, who has agreed to head the committee to direct the fund raising, said that the proposed scholarship would be used to train qualified youths in public health administration. Dr. Bredeck died October 4.

NEW YORK

Seminar in Urology.—The American Urological Association through the northeastern section of the country will conduct an intensive postgraduate course in urology Jan. 3-8, 1949 under the auspices of the University of Buffalo School of Medicine. The anatomy, physiology, bacteriology, biochemistry and pathology of the urinary tract will be covered by teachers and clinicians from various clinics throughout the country. For information, write Dr. George E. Slotkin, Chairman, Medical Center Building, 333 Linwood Avenue, Buffalo 9, N. Y.

Roentgen Program in Hospitals.—In upstate New York there are one hundred and sixty-five general, nonprofit hospitals eligible to participate in the State Department of Health program of routine chest roentgen examination of persons admitted. Hospitals with 4,000 admissions or over are eligible to receive the loan of photoroentgen equipment and are paid 50 cents for the report of each admission roentgen examination. Hospitals of less than 4,000 admissions annually use their own equipment and receive $1 for each report. There were twenty-three hospitals participating in the program October 1; fifteen have annual admissions of 4,000 or more each, totaling 128,946 admissions, and eight have less than 4,000 annual admissions, each totaling 17,310 admissions. Applications have been approved and equipment purchased for loan to another sixteen eligible hospitals, and eight others are in the process of being approved. Of one hundred and sixty-five eligible general hospitals in upstate New York forty-seven are participating, are awaiting equipment or have made application.

New York City

Brickner Lecture on Cancer.—The fifteenth Walter M. Brickner Lecture will be given at the Hospital for Joint Diseases by Dr. Peyton Rous of the Rockefeller Institute for Medical Research December 9 at 8:30 p. m., on "Cancer as Accident."

Dr. Gerard to Give Gregory Lecture.—Dr. Ralph W. Gerard, professor of physiology, University of Chicago Medical School, will speak on "Physiology and Psychiatry" in the annual Monas S. Gregory lecture to be sponsored by New York University College of Medicine November 8 at 4 p. m. in the amphitheater of the Psychiatric Division of Bellevue Hospital.

Dr. Sheehan Appointed Scientific Director.—Dr. Donal Sheehan, formerly director of the Commonwealth Fund, has been appointed chairman of the Scientific Committee, New York University-Bellevue Medical Center, and professor and chairman of the department of anatomy at the New York University College of Medicine. He will direct the over-all program of teaching and research to be carried out at the center. Dr. Sheehan was a member of the faculty for ten years before assuming the directorship of the Commonwealth Fund a year ago. From September 1937 to October 1947 he was professor and chairman of the department of anatomy. He was one of the principal authors of the survey report in which was first outlined the plans for the medical center.

Laboratory of Nuclear Studies.—A $2,000,000 laboratory of nuclear studies was dedicated October 7 at Cornell University. It consists of the main building and a structure housing a 300-Mev synchrotron. There will be a staff of 18 faculty members, 24 other full time staff members, 11 graduate research assistants, and 6 part time or temporary technicians under the direction of Robert R. Wilson, Ph.D. The laboratory of nuclear studies was established in 1946 with Robert F. Bacher, Ph.D., as director. Dr. Wilson succeeded Dr. Bacher when the latter was appointed a member of the Atomic Energy Commission.

Schoenberg Lecture on Glaucoma.—Dr. John N. Evans of Brooklyn will deliver the Mark J. Schoenberg Memorial Lecture on "Circulatory Aspects of the Glaucoma Problem" at the New York Academy of Medicine, December 6 at 8 p. m., under the joint sponsorship of the New York Society for Clinical Ophthalmology and the National Society for the Prevention of Blindness. The lectureship was established as a memorial to Dr. Schoenberg's interest and original work in the control of glaucoma. The lecture will be preceded by an illustrated talk on "Observations on the Anterior Chamber Angle with the Gonioprism" by Dr. Harvey E. Thorpe of Pittsburgh.

Personals.—Dr. Robert Gutierrez recently returned from a lecture trip to South America, where he conducted operative clinics in the capitals of several countries. Dr. Gutierrez was made honorary member of the urological associations of Colombia, Peru, Chile, Argentina, Uruguay, Brazil and the Venezuelan Surgical Association, the Peruvian Academy of Surgery and the Brazilian College of Surgeons.——Dr. Sidney M. Samis has been appointed assistant director of Mount Sinai Hospital. Dr. Samis, who was a medical corps captain during the war, has served in administrative posts at Montefiore Hospital for Chronic Diseases and the Union Health Center in New York. He is a graduate of St. Louis (Mo.) University Medical School, 1941.——Dr. William Dock, professor of medicine at the Long Island College of Medicine, served as physician in chief pro tempore at the Peter Bent Brigham Hospital, Boston, October 25-30. While there he delivered the E. Stanley Emery Jr. Memorial Lecture on "Peptic Ulcer and Periodic Visceral Pain."

OHIO

Physicians' Fund Aids Medical School.—The Society of General Physicians of Cincinnati established a fund in 1947 for the purpose of making small funds available for the benefit of the University of Cincinnati College of Medicine. The fund is made up of 75 per cent of net proceeds of the postgraduate program of the society. In the past year the following disbursements were made by the dean, who administers the fund: $1,200 for a teaching fellow in the department of obstetrics; $400 for a precision balance for the gastric laboratory and $1,200 to the cardiac laboratory.

Campaign Against Brucellosis.—The Ohio State Medical Association and the State Veterinary Medical Association have initiated a joint campaign to warn farm people of the dangers of brucellosis. The committee on rural health of the state medical association has published a folder which relates the symptoms of brucellosis in man, its menace to human health and steps to be taken to protect the farm family. A companion folder, which gives the latest known facts of diseases among farm animals, is being published by the state veterinary medical association committee on brucellosis. Both folders are to be distributed to farm organizations and county health officials.

TEXAS

Lecture in Neurology.—Dr. Francis C. Grant, professor of neurosurgery, University of Pennsylvania School of Medicine, Philadelphia, will give the James Greenwood Lecture in neurology and neurosurgery at the University of Texas Medical Branch, Galveston, December 6.

University Appointment.—Wiktor W. Nowinski, Ph.D., who has been doing research on enzyme factors in brain metabolism at the University of Texas Medical Branch, Galveston, has been appointed associate professor of neurochemistry.

Sweeney Diabetic Foundation.—This foundation has launched a campaign to raise $100,000 for establishment of a camp for diabetic children and a research laboratory for diabetic and allied research. The camp is to be on 400 acres of land near Gainesville, and the laboratory is to be located in Gainesville. The foundation was organized a year ago by the citizens of Gainesville and named for Dr. J. Shirley Sweeney, who was persuaded to become director of the enterprise. The project has been endorsed by the Cooke County Medical Society.

WASHINGTON

State Medical Election.—At the annual meeting of the Washington State Medical Association in October, Dr. Harold E. Nichols, Seattle, was installed as president. Dr. Donald G. Corbett, Spokane, was chosen president-elect and Dr. James W. Haviland, Seattle, secretary-treasurer. Drs. Ross D. Wright, Tacoma, and Raymond L. Zech, Seattle, were named delegates to the American Medical Association, with Drs. Frank H. Douglass and Vernon W. Spickard, both of Seattle, named as alternates. The next annual convention will be held in Seattle.

GENERAL

Panamerican Convention on Medical Education Postponed.—The secretary of the Panamerican Convention on Medical Education, which was to meet in Lima, Peru, December 3-13, announces that the meeting has been postponed until next year, probably some time in February.

Award to Designer of Lenses.—David S. Grey, Boston designer for lenses for television and receiving sets and microscopes for medical research, received the Adolph Lomb Medal of 1948 at the recent annual meeting of the Optical Society of America in Detroit. As part of his work he has designed new types of microscopic lenses for accurate photography of medical specimens in invisible ultraviolet light.

Tropical Medicine Society Meetings.—The National Malaria Society will meet conjointly with the American Society of Tropical Medicine and the American Society of Parasitologists at the Hotel Roosevelt, New Orleans, December 5-8. The National Malaria Society has scheduled four scientific sessions including a panel discussion on malaria and a joint meeting with the American Society of Parasitologists and the American Society of Tropical Medicine.

Society Election.—At the summer meeting of the American Proctologic Society, the following officers were elected: Harry E. Bacon, Philadelphia, president; Vernon G. Jeurink, Denver, president-elect; Hoyt R. Allen, Little Rock, treasurer, and W. Wendell Green, Toledo, secretary. Since Dr. Jeurink's death July 6, the council has chosen Dr. Louis E. Moon, Omaha, as president-elect.

Conference on Electronic Instrumentation.—A three day conference on the use of electronic instrumentation in the fields of nucleonics and medicine will be held in the Engineering Societies Building, New York, November 29 to December 1, under the auspices of the Institute of Electrical Engineers and the Institute of Radio Engineers. Addresses of the first day will place emphasis on the medical requirements of electronic instruments. A large display of nuclear radiation instruments has been provided by the Atomic Energy Commission.

Impostor Apprehended.—The impostor who was posing as a representative of the American Medical Association for the purpose of inspecting hospital laboratories (The Journal, October 23, page 602) was apprehended by military police at Fort Hamilton, Brooklyn, early in October and was released to civilian authorities. "Dr. Rumrick" appeared at the Station Hospital, Fort Hamilton. The commanding officer at the hospital, having previously received a telegraphic warning which was sent to U. S. Army hospitals in the New York area, notified the military police. The impostor has pleaded guilty.

Societies Appoint Executive Secretaries.—William C. Stronach has been appointed executive secretary of the American College of Radiology, which has headquarters in the Civic Opera Building, Chicago, to succeed Mac F. Cahal, who has become executive secretary of the American Academy of General Practice. Mr. Stronach was formerly Mr. Cahal's assistant. Mr. Cahal has been retained as consultant to the American College of Radiology with the title of general counsel. Headquarters of the American Academy of General Practice are located at 231 West 47th Street, Kansas City, Mo.
